This work is provided “as is,” and the publisher disclaims any and all warranties, express or implied, including any warranties as to accuracy, comprehensiveness, or currency of the content of this work.

This work is no substitute for individual patient assessment based upon health care professionals’ examination of each patient and consideration of, among other things, age, weight, gender, current or prior medical conditions, medication history, laboratory data, and other factors unique to the patient. The publisher does not provide medical advice or guidance, and this work is merely a reference tool. Health care professionals, and not the publisher, are solely responsible for the use of this work including all medical judgments and for any resulting diagnosis and treatments.

Given continuous, rapid advances in medical science and health information, independent professional verification of medical diagnoses, indications, appropriate pharmaceutical selections and dosages, and treatment options should be made and health care professionals should consult a variety of sources. When prescribing medication, health care professionals are advised to consult the product information sheet (the manufacturer's package insert) accompanying each drug to verify, among other things, conditions of use, warnings, and side effects, and identify any changes in dosage schedule or contraindications, particularly if the medication to be administered is new, is infrequently used, or has a narrow therapeutic range. To the maximum extent permitted under applicable law, no responsibility is assumed by the publisher for any injury and/or damage to persons or property, as a matter of products liability, negligence law or otherwise, or from any reference to or use by any person of this work.

Preface

The impact of the coronavirus pandemic on mental health and well-being is felt worldwide. As most of the world focused on survival of the coronavirus, mental health needs were unattended. Now, we are faced with untreated mental disorders complicated by the mental health consequences of the pandemic. While the negative economic and social consequences of the pandemic are well-known, research is just emerging detailing the significant aftereffects to children, adults, families, and communities. Anxiety and contamination fears plague children as they return to schools. Depression, intimate partner violence, and anxiety are on the rise in the adult population. The pandemic accelerated economic inequality affecting underserved and low-income communities.

Virtual health care access was available to people in communities with internet access. Many rural communities did not have internet access. In-person health care was available for only emergency treatment with little access to prevention and treatment of chronic disorders. Since the pandemic is having such a world wide impact on mental health, COVID-19 discussions are woven throughout the chapters.

The primary purpose of this text is to prepare nurses to care for persons with mental health issues and problems. Mental disorders are recognized as one of the major burdens to society. These disorders contribute to high morbidity and mortality rates, as well as lost economic productivity. One in five persons will suffer a mental disorder in a lifetime. The duty of every nurse in all settings is to have the knowledge and skills to implement evidence-based practice for persons with mental disorders. As a result of the pandemic, it is more critical than ever that nurses are prepared to care for persons suffering from stress, depression, anxiety, and trauma.

The seventh edition of *Psychiatric Nursing: Contemporary Practice* evolved during the pandemic as virtual mental health care became the norm and mental

health care providers were challenged to deliver innovative quality care in an electronic environment. As electronic access to mental health applications increased, it became obvious that nurses would be key players in the expansion of the delivery of mental health care. This text includes discussions and recommendations on the use of electronic platforms in nursing practice and their ethical implications.

The special needs and mental health issues of the lesbian, gay, bisexual, transgender, queer or questioning (LGBTQ) communities have long been ignored. Stigmatization and discrimination can prevent persons who identify as LGBTQ from accessing quality mental health care and, in turn, contribute to mental health problems. This text discusses the mental health needs and care of persons who identify as LGBTQ. Gender-neutral, bias-free language is used throughout the text.

Based on the request of several reviewers, a new chapter is included on the care of military veterans. This chapter discusses the relationship between the military experience and the health care needs of veterans. The mental health issues and disorders of veterans are explained within the context of their military experiences. There is also a discussion of the role of the Veterans Health Administration in providing mental health care to veterans.

TEXT ORGANIZATION

The first three units of *Psychiatric Nursing: Contemporary Practice, Seventh Edition* present the conceptual underpinnings and principles of psychiatric–mental health nursing. In Unit I, students are introduced to mental health nursing care in contemporary society as an evidenced-based practice. Students are introduced to stigma and recovery in Chapter 2, which sets the stage for a more detailed discussion of recovery in Chapter 9.

Unit II provides the theoretical foundations of psychiatric nursing including several nursing and recovery frameworks as well as biological and psychosocial theoretical underpinnings. Unit III is the essence of psychiatric–mental health nursing with a detailed discussion of the psychiatric–mental health nursing process including explanations of evidence-based interventions. Therapeutic communication skills, psychopharmacology, cognitive interventions, group interventions, and family assessment and interventions are presented in a clear and understandable language. This unit prepares the student for making clinical judgments and sound decisions in caring for patients.

Units IV and V present mental health promotion and prevention content, including comprehensive chapters on stress and mental health, crises, violence, and suicide prevention. Unit VI discusses the care of persons with mental disorders within a recovery-oriented, evidence-based practice.

Units VII and VIII focus on the assessment and care of children and older adults with mental disorders characteristic of each age group. Unit IX introduces the student to a new chapter, Care of Veterans with Mental Health Needs as well as caring for persons who are experiencing homelessness and co-occurring mental disorders. Chapter 43 addresses the care of persons with selected medical disorders that are typical of persons with mental disorders.

The text presents complex concepts in easy-to-understand language with multiple examples and explanations. Students find the text easy to comprehend, filled with meaningful information, and applicable to all areas of nursing practice.

PEDAGOGICAL FEATURES

The seventh edition of *Psychiatric Nursing: Contemporary Practice* incorporates a multitude of pedagogical features to focus and direct student learning, including the following:

By including evidence-based content from which students can draw valid inferences, students can develop clinical judgment and decision-making skills.

- **Expanded Table of Contents** allows readers to find and refer to concepts from one location.
- **Learning Objectives, Key Terms, and Key Concepts** in the chapter openers cue readers on what will be encountered and what is important to understand in each chapter.
- **Summary of Key Points** listed at the end of each chapter provides quick access to important chapter content to facilitate study and review.
- **Critical Thinking Challenges** ask questions that require students to think critically about chapter content and apply psychiatric nursing concepts to nursing practice.
- **Movie Viewing Guides** list current examples of movies that depict various mental health disorders and that are widely available. Viewing points are provided to serve as a basis for discussion in class and among students.

SPECIAL FEATURES

Case Studies threaded in the disorder chapters are related to the Nursing Care

Plan and Therapeutic Dialogue features, giving students the opportunity to apply content. Cases will come from the Patient Experience Videos, to help tie content from the book to the videos. For chapters without a corresponding video, a new case study has been created. Exposure to patients builds student confidence and provides a seamless transition to the practice world.

- **Wellness Challenges** threaded in disorder chapters focus on keeping patients healthy and utilize case study “patient” information to apply the content.
- **Integration with Primary Care**, also threaded in disorder chapters and utilizing case study content, addresses integration of psychiatric disorders with basic health needs blended.
- **NCLEX Notes** help students focus on important application areas to prepare for the NCLEX.
- **Emergency Care Alerts** highlight important situations in psychiatric nursing care that the nurse should recognize as emergencies.
- **Research for Best Practice** boxes highlight today’s focus on evidence-based practice for best practice, presenting findings and implications of studies that are applicable to psychiatric nursing practice.
- **Therapeutic Dialogue** boxes compare and contrast therapeutic and nontherapeutic conversations to encourage students by example to develop effective communication skills.
- **Psychoeducation Checklists** identify content areas for patient and family education related to specific disorders and their treatment. These checklists support critical thinking by encouraging students to develop patient-specific teaching plans based on chapter content.
- **Clinical Vignette** boxes present reality-based clinical portraits of patients who exhibit the symptoms described in the text. Questions are posed to help students express their thoughts and identify solutions to issues presented in the vignettes.
- **Medication Profile** boxes present a thorough picture of commonly prescribed medications for patients with mental health problems. The profiles complement the text discussions of biologic processes known to be associated with various mental health disorders.
- **Key Diagnostic Characteristics** summaries describe diagnostic criteria, target symptoms, and target associated findings for select disorders, adapted from the *DSM-5* by the American Psychiatric Associations.
- **Concept Mastery Alerts** clarify common misconceptions as identified by Lippincott’s Adaptive Learning Powered by prepU.
- **Evidence-Based Nursing Practice of Persons with Selected Mental Health Disorders** sections provide an in-depth study of the more commonly occurring major psychiatric disorders.
- **Patient Education** , **family** , and **emergency**  icons highlight content related to these topics to help link concepts to practice.

TEACHING/LEARNING PACKAGE

To facilitate mastery of this text's content, a comprehensive teaching and learning package has been developed to assist faculty and students.

Instructor Resources

Tools to assist you with teaching your course are available upon adoption of this text at <http://thePoint.lww.com/Boyd7e>

- **A Test Generator** lets you put together exclusive new tests from a bank containing hundreds of questions to help you in assessing your students' understanding of the material. Test questions link to chapter learning objectives.
- **PowerPoint Presentations** provide an easy way for you to integrate the textbook with your students' classroom experience, either via slide shows or handouts. Multiple-choice and true/false questions are integrated into the presentations to promote class participation and allow you to use i-clicker technology.
- **An Image Bank** lets you use the photographs and illustrations from this textbook in your PowerPoint slides or as you see fit in your course.
- **Case Studies** with related questions (and suggested answers) give students an opportunity to apply their knowledge to a client case similar to one they might encounter in practice.
- **Pre-Lecture Quizzes** (and answers) are quick, knowledge-based assessments that allow you to check students' reading.
- **Guided Lecture Notes** walk you through the chapters, objective by objective.
- **Discussion Topics** (and suggested answers) can be used as conversation starters or in online discussion boards.
- **Plus Assignments, Lesson Plans, QSEN Competency Maps, Strategies for Effective Teaching, and Syllabi.**

Student Resources

An exciting set of free resources is available to help students review material and become even more familiar with vital concepts. Students can access all these resources at <http://thePoint.lww.com/Boyd6e> using the codes printed in the front of their textbooks.

- **NCLEX-Style Review Questions** for each chapter help students review important concepts and practice for the NCLEX.

- **Watch & Learn Videos**, *Lippincott Theory to Practice Video Series: Psychiatric–Mental Health Nursing*, includes videos of true-to-life patients displaying mental health disorders, allowing students to gain experience and a deeper understanding of mental health patients.
- **Journal Articles** provided for each chapter offer access to current research available in Wolters Kluwer journals.
- **Movie Viewing Guides** list current examples of movies that depict various mental health disorders and that are widely available. Viewing points are provided to serve as a basis for discussion in class and among students.

A FULLY INTEGRATED COURSE EXPERIENCE

We are pleased to offer an expanded suite of digital solutions and ancillaries to support instructors and students using *Psychiatric Nursing: Contemporary Practice*, Seventh Edition. To learn more about any solution, please contact your local Wolters Kluwer representative.

Lippincott **CoursePoint+**

The same trusted solution, innovation and unmatched support that you have come to expect from *Lippincott CoursePoint+* is now enhanced with more engaging learning tools and deeper analytics to help prepare students for practice. This powerfully integrated, digital learning solution combines learning tools, case studies, virtual simulation, real-time data, and the most trusted nursing education content on the market to make curriculum-wide learning more efficient and to meet students where they're at in their learning. And now, it's easier than ever for instructors and students to use, giving them everything they need for course and curriculum success!

Lippincott CoursePoint+ includes the following:

- Engaging course content provides a variety of learning tools to engage students of all learning styles.
- A more personalized learning approach, including adaptive learning powered by PrepU, gives students the content and tools they need at the moment they need it, giving them data for more focused remediation and helping to boost their confidence.
- Varying levels of case studies, virtual simulation, and access to Lippincott Advisor help students learn the critical thinking and clinical judgment skills to help them become practice-ready nurses.
- Unparalleled reporting provides in-depth dashboards with several data points to track student progress and help identify strengths and weaknesses.

- Unmatched support includes training coaches, product trainers, and nursing education consultants to help educators and students implement CoursePoint with ease.

vSim for Nursing

vSim for Nursing, jointly developed by Laerdal Medical and Wolters Kluwer Health, offers innovative scenario-based learning modules consisting of web-based virtual simulations, course learning materials, and curriculum tools designed to develop critical thinking skills and promote clinical confidence and competence. vSim for Nursing | Mental Health includes 10 mental health scenarios authored by the National League for Nursing. Students can progress through suggested readings, pre- and post-simulation assessments, documentation assignments, and guided reflection questions, and will receive an individualized feedback log immediately upon completion of the simulation. Throughout the student learning experience, the product offers remediation back to trusted Lippincott resources, including Lippincott Nursing Advisor and Lippincott Nursing Procedures—two online, evidence-based, clinical information solutions used in healthcare facilities throughout the United States. This innovative product provides a comprehensive patient-focused solution for learning and integrating simulation into the classroom.

Contact your Wolters Kluwer sales representative or visit <http://thepoint.lww.com/vsim> for options to enhance your mental health nursing course with vSim for Nursing.

Lippincott DocuCare

Lippincott DocuCare combines web-based academic electronic health record (EHR) simulation software with clinical case scenarios, allowing students to learn how to use an EHR in a safe, true-to-life setting, while enabling instructors to measure their progress. Lippincott DocuCare's nonlinear solution works well in the classroom, simulation lab, and clinical practice.

Contact your Wolters Kluwer sales representative or visit <http://thepoint.lww.com/DocuCare> for options to enhance your mental health nursing course with DocuCare.

Acknowledgments

This text is a result of many long hours of diligent work by the contributors, editors, and assistants. Psychiatric nurses are constantly writing about and discussing new strategies for caring for persons with mental disorders. Consumers of mental health services provided directions for nursing care and validated the importance of nursing interventions. I wish to acknowledge and thank these individuals.

Jamie Blum and Julie Vitale of Wolters Kluwer were extraordinary partners in this project. I want to especially acknowledge their attention to detail and their commitment to excellence. They provided direction, support, and valuable input throughout this project. They were extraordinary partners during revision of this update. They brought a broad knowledge base and extreme patience during the whole update process. I want to thank Ann Francis for the organizational skills that kept the project on target. This text would not be possible without Indu Jawwad and the highly committed team of Lumina Datamatics.

Contents

UNIT I MENTAL HEALTH CARE IN CONTEMPORARY SOCIETY

1 Psychiatric–Mental Health Nursing and Evidence-Based Practice

Introduction

The Past and Present

Evolution of Mental Health Recovery

Contemporary Mental Health Care

2 Mental Health and Mental Disorders: Fighting Stigma and Promoting Recovery

Introduction

Mental Health and Wellness

Overview of Mental Health Disorders

Recovery from Mental Illness

3 Cultural and Spiritual Issues Related to Mental Health Care

Introduction

Cultural and Linguistic Competence

Cultural and Social Factors and Beliefs About Mental Illness

Spirituality, Religion, and Mental Illness

4 Patient Rights and Legal Issues

Introduction

Self-Determinism: A Fundamental Right and Need

Protection of Patient Rights

Treatment and Patient Rights

Privacy and Confidentiality

Criminal Judicial Processes

Accountability for Nurses and Other Mental Health Care

Professionals

5 Mental Health Care in the Community

Introduction

Defining the Continuum of Care

Mental Health Services in a Continuum of Care

Recovery-Oriented Rehabilitation Settings

Alternative Housing Arrangements

Integrated Care

Managed Care

Nursing Practice in the Continuum of Care

UNIT II FOUNDATIONS OF PSYCHIATRIC NURSING

6 Ethics, Standards, and Nursing Frameworks

Introduction

Ethics of Psychiatric Nursing

Scope and Standards of Practice

The Biopsychosocial Framework

Tools of Psychiatric Nursing Practice

Challenges of Psychiatric Nursing

7 Psychosocial Theoretic Basis of Psychiatric Nursing

Introduction

Psychodynamic Theories
Cognitive-Behavioral Theories
Developmental Theories
Social Theories
Nursing Theories

8 Biologic Foundations of Psychiatric Nursing

Introduction
Neuroanatomy of the Central Nervous System
Neurophysiology of the Central Nervous System
Studies of the Biologic Basis of Mental Disorders
Diagnostic Approaches

9 Recovery Framework for Mental Health Nursing

Introduction
Mental Health Recovery
Recovery Interventions
Barriers to Recovery
Societal Role in Promoting a Recovery-Oriented Environment
Recovery-Oriented Psychiatric–Mental Health Nursing Practice

UNIT III CONTEMPORARY PSYCHIATRIC NURSING PRACTICE

10 Communication and the Therapeutic Relationship

Introduction
Self-Awareness
Effective Communication
Therapeutic Communication Strategies and Techniques
Considerations for Effective Communication and Relationships
Communication Considerations for Patients with Mental Health Challenges

The Nurse–Patient Relationship
Examples of Strategies Related to Therapeutic Relationships

11 The Psychiatric–Mental Health Nursing Process

Introduction
Recovery-Oriented Psychiatric–Mental Health Nursing
Assessment
Using Clinical Judgment
Developing Recovery Goals and Outcomes
Recovery-Oriented Nursing Interventions
Evaluating Outcomes

12 Psychopharmacology, Dietary Supplements, and Biologic Interventions

Introduction
Psychiatric Medications
Psychopharmacology
Phases of Drug Treatment and The Nurse’s Role
Major Psychopharmacologic Drug Classes
Integrative and Complementary Health Care
Other Biologic Treatments
The Issue of Adherence

13 Cognitive Interventions in Psychiatric Nursing

Introduction
Development of Cognitive Therapies
Cognitive Therapy Models
Use of Cognitive Therapies in Psychiatric Nursing

14 Group Interventions

Introduction
Preparing to Lead a Group
Leading a Group

Types of Groups
Common Nursing Intervention Groups

15 Family Assessment and Interventions

Introduction
Changing Family Structure
Family Mental Health
Comprehensive Family Assessment
Family Interventions

UNIT IV MENTAL HEALTH ACROSS THE LIFE SPAN

16 Mental Health Promotion for Children and Adolescents

Introduction
Childhood and Adolescent Mental Health
Common Problems in Childhood
Risk Factors for Childhood Psychopathology
Intervention Approaches

17 Mental Health Promotion for Young and Middle-Aged Adults

Introduction
Mental Health in Young and Middle Adulthood
Common Challenges in Adulthood
Mental Disorders in Young and Middle Adulthood
Risk Factors for Young and Middle Adulthood Psychopathology
Protective Factors
Intervention Approaches

18 Mental Health Promotion for Older Adults

Introduction
Older Adult Mental Health
Common Challenges in Older Adulthood

Risk Factors for Older Adult Psychopathology
Protective Factors for Mental Illness in Older Persons
Intervention Approaches
Positive Mental Aging

UNIT V PREVENTION OF MENTAL DISORDERS

19 Stress and Mental Health

Introduction
Biologic Perspectives of Stress
Psychosocial Perspectives of Stress
Responses to Stress
Coping
Adaptation
Nursing Care for the Person Experiencing Stress

20 Management of Anger, Aggression, and Violence

Introduction
Anger
Aggression and Violence
Promoting Safety and Preventing Violence
Research and Policy Initiatives

21 Crisis, Loss, Grief, Bereavement, and Disaster Management

Introduction
Crisis
Evidence-Based Nursing Care of Person in Crisis
Therapeutic Relationship
Mental Health Nursing Interventions
Loss, Grief, and Bereavement
Evidence-Based Nursing Care of Person in Grief
Disaster and Terrorism

Evidence-Based Nursing Care of Persons Experiencing Disasters

22 Suicide Prevention: Screening, Assessment, and Intervention

Introduction

Suicide and Suicide Attempt

Treatment and Nursing Care for Suicide Prevention

Nurses' Reflection

23 Mental Health Care for Survivors of Violence

Introduction

Types of Violence and Abuse

Theories of Violence

The Role of Technology in Caring for Survivors of Intimate Partner Violence

Therapeutic Relationship

Evidence-Based Nursing Care for Persons Experiencing Violence

Treatment for the Abuser

UNIT VI CARE AND RECOVERY FOR PERSONS WITH MENTAL DISORDERS

24 Schizophrenia and Related Disorders: Nursing Care of Persons with Thought Disorders

Introduction

Schizophrenia Spectrum Disorders Overview

Schizophrenia

Recovery-Oriented Care for Persons with Schizophrenia

Evidence-Based Nursing Care of Persons with Schizophrenia

Clinical Judgment

Therapeutic Relationship

Mental Health Nursing Interventions

Schizoaffective Disorder

Delusional Disorder
Other Psychotic Disorders

25 Depression: Nursing Care of Persons with Depressive Moods and Suicidal Behavior

Introduction
Mood and Depression
Depressive Disorders Overview
Major Depressive Disorder
Recovery-Oriented Care for Persons with Depressive Disorders
Evidence-Based Nursing Care of Persons with Depressive Disorder
Clinical Judgment
Therapeutic Relationship
Mental Health Nursing Interventions
Other Depressive Disorders

26 Bipolar Disorders: Nursing Care of Persons with Mood Lability

Introduction
Mania
Bipolar Disorders Overview
Bipolar I Disorder
Recovery-Oriented Care for Persons with Bipolar Disorder
Evidence-Based Nursing Care of Persons with Bipolar Disorder
Clinical Judgment
Therapeutic Relationship
Mental Health Nursing Interventions
Other Bipolar and Related Disorders

27 Anxiety Disorders: Nursing Care of Patients with Anxiety, Phobia, and Panic

Introduction

Normal Versus Abnormal Anxiety Response
Phobias
Anxiety Disorders Overview
Panic Disorder
Recovery-Oriented Care for Persons with Panic Disorder
Evidence-Based Nursing Care of Persons with Panic Disorder
Clinical Judgment
Therapeutic Relationship
Mental Health Nursing Interventions
Generalized Anxiety Disorder
Other Anxiety Disorders

28 Obsessive-Compulsive and Related Disorders: Nursing Care of Persons with Obsessions and Compulsions

Introduction
Obsessions and Compulsions
Obsessive-Compulsive and Related Disorders: Overview
Obsessive-Compulsive Disorder
Recovery-Oriented Care for Persons with Obsessive-Compulsive Disorder
Evidence-Based Nursing Care of Persons with Ocd
Clinical Judgment
Therapeutic Relationship
Mental Health Nursing Interventions
Evaluation and Treatment Outcomes
Other Related Obsessive-Compulsive Disorders

29 Trauma- and Stressor-Related Disorders: Nursing Care of Persons with Posttraumatic Stress and Other Trauma-Related Disorders

Psychiatric–Mental Health Nursing and
Evidence-Based Practice

Patricia E. and Freed Mary Ann Boyd

KEYCONCEPTS

- evidence-based practice
- psychiatric–mental health nursing

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Identify the dynamic scope of psychiatric–mental health nursing practice.
2. Relate the history of psychiatric–mental health nursing to contemporary nursing practice.
3. Discuss the importance of evidence-based psychiatric–mental health nursing practice in all health care settings.
4. Outline the evolution of recovery in mental health care.
5. Discuss the impact of recent legislative and policy changes in the delivery of mental health evidence.

KEY TERMS

- Asylum
- Deinstitutionalization
- Institutionalization
- Moral treatment
- Neurosis
- Psychoanalysis
- Psychosis

INTRODUCTION

Everyone experiences emotional and mental health issues at some time in their lives. During periods of illness and stress, mental health issues often become overwhelming to individuals and their families. Every nurse provides mental health interventions, no matter the practice site. Nurses in acute care settings are likely to care for persons in mental health crises because medical problems are treated before any mental health issues (e.g., physical injuries from a suicide

attempt are treated before the underlying depression). Like anyone else, people with psychiatric disorders seek health care for their medical illnesses. The stress of the medical illness can also exacerbate psychiatric symptoms.

Psychiatric nurses care for patients with a wide range of emotional problems and mental disorders ([Box 1.1](#)). These nurses, specializing in mental health nursing, are experts in caring not only for persons with a primary diagnosis of a mental disorder but also for those with self-concept and body image issues, developmental crises, co-occurring disorders, end-of-life changes, and emotional stress related to illness, disability, or loss. It is a psychiatric nurse who is called when violence, suicide, or a disaster erupts. In this text, the terms *psychiatric nursing* and *psychiatric–mental health nursing* are used interchangeably. The standards of practice are discussed in [Chapter 6](#).

BOX 1.1

Psychiatric–Mental Health Nursing Phenomena of Concern

Phenomena of concern for psychiatric–mental health nurses are dynamic, exist in all populations across the life span, and include but are not limited to the following:

- Promotion of optimal mental and physical health and well-being
- Prevention of mental and behavioral distress and illness
- Promotion of social inclusion of mentally and behaviorally fragile individuals
- Co-occurring mental health and substance use disorders
- Co-occurring mental health and physical disorders
- Alterations in thinking, perceiving, communicating, and functioning related to psychological and physiologic distress
- Psychological and physiologic distress resulting from physical, interpersonal, and/or environmental trauma or neglect
- Psychogenesis and individual vulnerability
- Complex clinical presentations confounded by poverty and poor, inconsistent, or toxic environmental factors
- Alterations in self-concept related to loss of physical organs and/or limbs, psychic trauma, developmental conflicts, or injury
- Individual, family, or group isolation and difficulty with interpersonal relations
- Self-harm and self-destructive behaviors including mutilation and suicide
- Violent behavior including physical abuse, sexual abuse, and bullying
- Low health literacy rates contributing to treatment nonadherence

KEYCONCEPT Grounded in nursing theories, **psychiatric–mental health nursing** is defined as the “nursing practice specialty committed to promoting mental health through the assessment, diagnosis, and treatment of behavioral problems, mental disorders, and comorbid conditions across the life span. Psychiatric–mental health nursing intervention is an art and a science, employing purposeful use of self and a wide range of nursing, psychosocial, and neurobiological evidence to produce effective outcomes” (American Nurses Association, American Psychiatric Nurses Association, & International Society of Psychiatric–Mental Health Nurses, 2014, p. 1).

THE PAST AND PRESENT

Psychiatric nursing has a history that can be traced back to the early days of nursing practice. Today, the specialty has developed into one of the core mental health professions with an emphasis on evidence-based practice.

Early Founders

The roots of contemporary psychiatric–mental health nursing can be traced to Florence Nightingale’s holistic view of a patient who lives within a family and community. She was especially sensitive to human emotions and recommended interactions that today would be classified as therapeutic communication (see [Chapter 10](#)). For example, this early nursing leader’s intervention for reducing anxiety about an illness was to encourage independence and self-care (Nightingale, 1859).

Linda Richards, the first trained nurse in the United States, opened the Boston City Hospital Training School for Nurses in 1882 at McLean Hospital, a mental health facility ([Box 1.2](#)) (Cowles, 1887). Employees of McLean were recruited into the nursing program to learn to provide physical care for patients with mental disorders who developed medical illnesses. In 1913, Effie Taylor integrated psychiatric nursing content into the curriculum at Johns Hopkins’ Phipps Clinic. Taylor, like Nightingale before her, encouraged nurses to avoid the dichotomy of mind and body (Church, 1987). The first psychiatric nursing textbook, *Nursing Mental Disease*, was written by Harriet Bailey in 1920 (Bailey, 1920). Gradually, nursing education programs in psychiatric hospitals were phased into mainstream nursing education programs.

BOX 1.2

History of Psychiatric–Mental Health Nursing

- 1882** First training school for psychiatric nursing at McLean Asylum by E. Cowles; first nursing program to admit men
- 1913** First nurse-organized program of study for psychiatric training by Euphemia (Effie) Jane Taylor at Johns Hopkins Phipps Clinic
- 1914** Mary Adelaide Nutting emphasized nursing role development
- 1920** First psychiatric nursing text published, *Nursing Mental Disease*, by Harriet Bailey
- 1950** Accredited schools required to offer a psychiatric nursing experience
- 1952** Publication of Hildegard E. Peplau's *Interpersonal Relations in Nursing*
- 1954** First graduate program in psychiatric nursing established at Rutgers University by Hildegard E. Peplau
- 1963** *Perspectives in Psychiatric Care and Journal of Psychiatric Nursing* published
- 1967** *Standards of Psychiatric–Mental Health Nursing Practice* published; American Nurses Association (ANA) initiated the certification of generalists in psychiatric–mental health nursing
- 1979** *Issues in Mental Health Nursing* published; ANA initiated the certification of specialists in psychiatric–mental health nursing
- 1980** *Nursing: A Social Policy Statement* published by the ANA
- 1982** *Revised Standards of Psychiatric and Mental Health Nursing Practice* issued by the ANA
- 1985** *Standards of Child and Adolescent Psychiatric and Mental Health Nursing Practice* published by the ANA
- 1987** *Archives of Psychiatric Nursing and Journal of Child and Adolescent Psychiatric and Mental Health Nursing* published
- 1994** *Statement on Psychiatric–Mental Health Clinical Nursing Practice and Standards of Psychiatric–Mental Health Clinical Nursing Practice* published
- 1996** Guidelines specifying course content and competencies published by the Society for Education and Research in Psychiatric–Mental Health Nursing
- 2000** *Scope and Standards of Psychiatric–Mental Health Nursing Practice* published
- 2003** A second advanced practice role, Psychiatric–Mental Health Nurse Practitioner, was delineated
- 2014** *Psychiatric–Mental Health Nursing: Scope and Standards of Practice* was revised to reflect the expanding role of psychiatric–mental health nurses practicing in a recovery-oriented environment.

Emergence of Modern Nursing Perspectives

As psychiatric–mental health nursing developed as a profession in the 20th century, modern perspectives of mental illness emerged, and these new theories profoundly shaped mental health care (see [Units II and III](#)). In 1952, Hildegard E. Peplau published the landmark work *Interpersonal Relations in Nursing* (Peplau, 1952). This publication introduced psychiatric–mental health nursing practice to the concepts of interpersonal relations and the therapeutic relationship. Peplau conceptualized nursing practice as independent of

physicians. The use of self as a nursing tool was outside the dominance of both hospital administrators and physicians.

Peplau also contributed to educational programs for psychiatric nursing, developing a specialty training program in psychiatric nursing—the first graduate nursing program—in 1954 at Rutgers University. Subspecialties began to emerge, focusing on children, adolescents, and older adults.

In 1967, the Division of Psychiatric and Mental Health Nursing Practice of the ANA published the first *Statement on Psychiatric Nursing Practice*. This publication was the first official sanction of a holistic approach of psychiatric–mental health nurses practicing in a variety of settings with a diverse clientele, emphasizing health promotion as well as health restoration. Since 1967, there have been several updates of the official practice statement that reflect the expansion of the role of psychiatric nurses with a delineation of functions.

Over the past century, psychiatric nursing practice expanded from the hospital to the community. Today in the United States, many nursing graduate degree programs offer specializations in psychiatric–mental health. Psychiatric nurses sit on corporate boards; serve in the armed forces; lead major health care initiatives; teach in major universities; and care for young and old people, families, and disadvantaged and homeless individuals. Psychiatric nursing is truly a versatile and rewarding field of nursing practice (Fig. 1.1).

FIGURE 1-1: Contemporary psychiatric–mental health nursing is a versatile and rewarding field of practice.

Evidence-Based Practice and Current Psychiatric

Nursing

Evidence-based practice is the standard of care in psychiatric nursing and mental health care. Clinical decisions that lead to high-quality patient outcomes are based on research and evidence-based theories, clinical expertise, and patient preferences and values. By combining data from various sources such as expert opinion, patient data, and clinical experiences, the nurse is able to be objective, yet open to new ideas. For example, using epidemiologic data alerts nurses to the increase in suicide rates among young men, that experts were predicting it, but that whether the trend continues or the factors behind it remains unknown.

KEYCONCEPT Evidence-based practice is a lifelong problem-solving approach to clinical practice that integrates

- a systematic search for and critical appraisal of the most relevant and best research (i.e., external evidence) to answer a burning clinical question;
- one's own clinical expertise, including use of internal evidence generated from outcomes management or evidence-based quality improvement projects, a thorough patient assessment, and evaluation and use of available resources necessary to achieve desired patient outcomes (Melnik & Fineout-Overholt, 2021, p. 8).

In an evidence-based approach, clinical questions are defined; evidence is discovered and analyzed; the research findings are applied in a practical manner and in collaboration with the patient; and outcomes are evaluated. One of the first steps is seeking out a mentor who can help through the evidence-based process because this approach requires using literature search skills, followed by careful reading and critiquing of the current studies and seeking the advice of experts in the field. A nurse might start with a clinical question, such as “Do social and environmental adversities effect recovery among persons with serious mental illness being treated in community mental health centers?”

The nurse and mentor will narrow the question and begin a critique of the literature. Even though the process results in directions for practice, the nurse will face many challenges. See [Box 1.3](#).

Box 1.3

Research for Best Practice: Associations between Two Domains of Social Adversity and Recovery among Persons with Serious Mental Illnesses Being Treated in Community Mental Health Centers.

Compton, M. T., Bakeman, R., Capulong, L., Pauselli, L., Alolayan, Y., Drisafio, A., King, K., Reed, T., Broussard, B., & Shim, R. (2020). Associations between two domains of social adversity and recovery among persons with serious mental illnesses being treated in community mental health centers. *Community Mental Health Journal*, 56(1), 22–31.

THE QUESTION: Do social and environmental adversities affect recovery among persons with serious mental illness being treated in CMHCs?

METHODS: Using a variety of methods to measure social adversity and symptom severity, the research team collected data on 300 persons with psychosis or mood disorders who were receiving treatment at five diverse community settings. After controlling for the effects of gender and diagnostic categories, statistical exploratory methods were applied to explain the relationships among a large number of variables.

FINDINGS: Social and economic adversities and home environment adversities jointly accounted for 3.4% of the variance in recovery. Symptom severity had a partial influence on social and economic adversities and a substantial influence on home environment adversities. The researchers concluded that recovery in persons with serious mental illness is influenced by their social and environmental circumstances as well as their symptoms.

IMPLICATIONS FOR NURSING: These findings validate the relationship between recovery and the determinants of mental health, highlighting the need for referrals to community services, and helping nurses realize that their advocacy obligations need to address social policies and programs directed at adversities that negatively impact recovery. The challenge will be in securing change as resources for helping vulnerable populations are targeted for reduction or elimination.

EVOLUTION OF MENTAL HEALTH RECOVERY

Throughout history, popular beliefs of the time served as the basis for understanding and treating people with mental illnesses. Prehistoric healers practiced an ancient surgical technique of removing a disk of bone from the skull to let out the evil spirits. In the early Christian period (1–100 CE), when sin or demonic possession was thought to cause mental disorders, clergymen treated patients, often through prescribed exorcisms. If such measures did not succeed, patients were excluded from the community and sometimes even put to death. Later in the medieval era (1000–1300 CE), contaminated environments were believed to cause *mental illness*. Consequently, individuals were removed from their “sick” environments and placed in protected **asylums**. [Table 1.1](#) provides a summary of historical events and correlating perspectives on mental health during the premodern treatment era (800 CE to the colonial period).

TABLE 1-1: PREMORAL TREATMENT ERA

Period	Beliefs About <i>Mental Illness</i>	Mental Health Care
Ancient times to 800 bce	Sickness was an indication of the displeasure of deities for sins; viewed as supernatural.	Persons with psychiatric symptoms were driven from homes and ostracized by relatives. When behavioral manifestations were viewed as supernatural powers, the persons who exhibited them were revered.
Periods of inquiry: 800 bce to 1 ce	Egypt and Greek periods of inquiry. Physical and mental health were viewed as interrelated. Hippocrates argued abnormal behaviors were due to brain disturbances. Aristotle related mental disorders to physical disorders.	Counseling, work, and music were provided in temples by priests to relieve the distress of those with mental disorders. Observation and documentation were a part of the care. The mental disorders were treated as diseases. The aim of treatment was to correct imbalances.
Early Christian and early medieval: 1–1000 ce	Power of Christian church grew. St. Augustine pronounced all diseases were ascribed to demons.	Persons with psychiatric symptoms were incarcerated in dungeons, beaten, and starved.
Later medieval: 1000–1300	In Western Europe, spirit of inquiry was dead. Healing was taken over by theologians and witch doctors. Persons with psychiatric symptoms were incarcerated in dungeons, beaten, and starved. In the Middle East, Avicenna said mental disorders are illnesses.	First asylums were built by Muslims. Persons with psychiatric symptoms were treated as being sick.
Renaissance: 1300–1600	In England, insane were differentiated from criminal. In colonies, mental illnesses were believed to be caused by	Persons with psychiatric symptoms who presented a threat to society were apprehended and locked up. There were no public

	demonic possession. Witch hunts were common.	provisions for persons with mental disorders except jail. Private hospitalization for the wealthy who could pay. Bethlehem Asylum was used as a private institution.
Colonial: 1700–1790	1751: Benjamin Franklin established Pennsylvania Hospital (in Philadelphia)—the first institution in United States to receive those with mental disorders for treatment and cure.	The beginnings of mental diseases were viewed as illness to be treated.
	1773: First public, freestanding asylum at Williamsburg, Virginia.	
	1783: Benjamin Rush categorized mental illnesses and began to treat mental disorders with medical interventions, such as bloodletting, mechanical devices.

Moral Treatment and Asylums

As evidence mounted that insanity was an illness and recovery was a possibility, existing primitive physical treatments, such as venesections (bloodletting) and gyrations (strapping patients to a rotating board), began to be viewed as either painful or barbaric (Fig. 1.2). With science not advanced enough to offer reasonable treatment approaches, a safe haven, or **asylum**, was considered the best option for treatment. In the moral treatment period (1790–1900), **moral treatment**, that is, the use of kindness, compassion, and a pleasant environment, was adopted. Individuals with mental disorders were routinely removed from their communities and placed in asylums, which were thought to be best for their safety and comfort (Fig. 1.3).

Figure 1-2: Interior of Bethlehem Asylum, London. (William Hogarth, 1697–1765. *The Rake's Progress: Scene in Bedlam.*) (From U.S. National Library of Medicine. *Images from the history of medicine*. Washington, DC: National Institutes of Health, Department of Health and Human Services. <http://resource.nlm.nih.gov/101394076>)

Figure 1-3: The Tranquilizer Chair of Benjamin Rush. A patient is sitting in a chair, his body immobilized, a bucket attached beneath the seat. (Benjamin Rush, 1746–1813. [1811]). (From U.S. National Library of Medicine. Images from the history of medicine. Washington, DC: National Institutes of Health, Department of Health and Human Services.
<http://resource.nlm.nih.gov/101436673>)

Despite the good intentions that may have been at the root of the moral treatment movement, within the asylums, patients were often treated inhumanely. A turning point occurred at Bicêtre, a men's hospital in France that had the distinction of being the worst asylum in the world, when physician Philippe Pinel (1745–1826) ordered the removal of the chains, stopped the abuses of drugging and bloodletting, and placed the patients under the care of physicians. Three years later, the same standards were extended to Salpêtrière, the asylum for female patients. At about the same time in England, William Tuke (1732–1822), a member of the Society of Friends, raised funds for a retreat for members who had mental disorders. The York Retreat was opened in 1796; restraints were abandoned, and sympathetic care in quiet, pleasant surroundings with some form of industrial occupation, such as weaving or farming, was provided (Fig. 1.4).

Figure 1-4: The perspective view of the north front of the retreat near York Samuel Tuke, 1784–1857 (1813). (From U.S. National Library of Medicine. Images from the history of medicine. National Institutes of Health, Department of Health and Human Services. <http://resource.nlm.nih.gov/101436033>)

In the United States, the Quakers were instrumental in stopping the practice of bloodletting; they also placed great emphasis on providing a proper religious atmosphere (Deutsch, 1949). The Quaker Friends Asylum was proposed in 1811 and opened 6 years later in Frankford, Pennsylvania (now Philadelphia), to become the second asylum in the United States. The humane and supportive rehabilitative attitude of the Quakers was seen as an extremely important influence in changing techniques of caring for those with mental disorders. As states were founded, new hospitals were opened that were dedicated to the care of patients with mental disorders.

Even with these hospitals, only a fraction of people with mental disorders received treatment. Those who were judged dangerous were hospitalized; those

deemed harmless or mildly insane were treated the same as other indigents and given no public support. In farm communities, as was the custom during the first half of the 19th century, poor and indigent individuals were often auctioned and bought by landowners to provide cheap labor. Landowners eagerly sought them for their strong backs and weak minds. The arrangement had its own economic usefulness because it provided the community with a low-cost way to care for people with mental illness. Some states used almshouses (poorhouses) for housing mentally ill individuals.

Public Funding, Dorothea Dix, and State Hospitals

Hospitals for individuals with mental illness were few because of financing; there were no funding mechanisms to support these large institutions. The first step in resolving the funding problem was defining responsibility—that is, which agency would be responsible for paying for care. In 1828, Horace Mann, a representative in the Massachusetts state legislature, saw his plea that the “insane are wards of the state” become a reality. State governments were mandated to assume financial responsibility for the care of people with mental illnesses (Beers, 1908).

After states were designated as being financially responsible for the treatment of their residents with mental illnesses, the next step was ensuring that each state appropriated funds. Dorothea Lynde Dix (1802–1887), a vigorous crusader for the humane treatment of patients with mental illness, was responsible for much of the reform of the mental health care system in the 19th century. Her solution was state hospitals. She first influenced the Massachusetts legislature to expand the Massachusetts State Hospital. Then, through public awareness campaigns and lobbying efforts, she managed to convince state after state to build hospitals. At the end of Dix’s long career, 20 states had responded directly to her appeals by establishing or enlarging state hospitals ([Box 1.4](#)).

BOX 1.4

Dorothea Lynde Dix

At nearly 40 years of age, Dorothea Dix, a retired school teacher living in Massachusetts, was solicited by a young theology student to help in preparing a Sunday school class for women inmates at the East

Cambridge Jail. Dix led the class herself and was shocked by the filth and dirt in the jail. She was particularly struck by the treatment of inmates with mental disorders. It was the dead of winter, and no heat was provided. When she questioned the jailer about the lack of heat, his answer was that “the insane need no heat.” The prevailing myth was that people with mental illnesses were insensible to extremes of temperature. Dix’s outrage initiated a long struggle in the reform of care.

An early feminist, Dix disregarded the New England role of a Puritan woman and diligently investigated the conditions of jails and the plight of the mentally ill. During the Civil War, she was appointed to the post of Superintendent of Women Nurses, the highest position held by a woman during the war.

Dorothea Lynde Dix.

Institutionalization and Its Outcomes

In state hospitals, **institutionalization**, the forced confinement of individuals for long periods of time in large facilities, became the primary treatment for more than 50 years (1900–1955). Institutions had little more to offer than food,

clothing, pleasant surroundings, and perhaps some means of employment and exercise. Outcomes of institutionalization were consistently negative. Thousands of people were warehoused within the walls of institutions for months and years with little hope of reentering society. Patients were socially isolated from their families and normal community life. The medical superintendent's major concern was the day-to-day operation of the large, aging physical structures. Untrained attendants who had little understanding of mental illnesses were responsible for the care, which was often cruel and inhumane. There were few educated nurses. Patients suffered adverse physical and psychological effects. There were few trained mental health providers. Early institutions eventually evolved into self-contained communities that produced their own food and made their own clothing. Institutionalization was a dismal failure.

Women had a particularly difficult time and often were institutionalized at the convenience of their fathers or husbands. Because a woman's role in the late 1800s was to function as a domestic extension of her husband, any behaviors or beliefs that did not conform to male expectations could be used to justify the claim of insanity. Women were literally held prisoner for years. In the asylums, women were psychologically degraded, used as servants, and physically tortured by male physicians and female attendants (Bly, 1887).

The relatively primitive and often misguided biologic treatments were unsuccessful. For example, the use of hydrotherapy, or baths, was an established procedure in mental institutions. Warm baths and, in some instances, ice cold baths produced calming effects for patients with mental disorders. However, this treatment's success was attributed to the restraint of patients during the bath rather than the physiologic responses that hydrotherapy produced. Baths were then applied indiscriminately and used as a form of restraint rather than a therapeutic practice.

Clifford Beers (1876–1943) recovered from a mental disorder, became an advocate of humane treatment, and published an autobiography, *A Mind That Found Itself* (1908), depicting his 3-year hospitalization experience in the 18th century. He was beaten; choked; imprisoned for long periods in dark, dank, padded cells; and confined for many days in a straightjacket. By 1909, Beers formed a National Committee for Mental Hygiene. Through the committee's advocacy efforts, other mental health services were initiated, such as child guidance clinics, prison clinics, and industrial mental health care.

Freud's Contribution

At the same time that the institutionalization movement was gaining strength, Sigmund Freud (1856–1939) and the psychoanalytic movement of the early 1900s exerted influence on the mental health community. Freud, trained as a neuropathologist, developed a personality theory based on unconscious motivations for behavior or drives. According to the Freudian model, normal development occurred in stages, with the first three—oral, anal, and genital—being the most important. Infants progressed through the oral stage, experiencing the world through symbolic oral ingestion; through the anal stage, in which toddlers develop a sense of autonomy through withholding; and on to the genital stage, in which a beginning sense of sexuality emerges within the framework of the oedipal relationship. If there was any interference in normal development, such as psychological trauma, psychosis or neurosis would develop (Freud, 1905).

Freud and his followers believed the primary causes of mental illnesses were psychological and a result of disturbed personality development and faulty parenting (Freud, 1927). Mental illnesses were categorized either as a **psychosis** (severe) or as a **neurosis** (less severe). A psychosis impaired daily functioning because of breaks in contact with reality. A neurosis was less severe, but individuals were often distressed about their problems. Soon, Freud's ideas represented the forefront of psychiatric thought and began to shape society's view of mental health care. Freudian ideology dominated psychiatric thought well into the 1970s.

Intensive **psychoanalysis**, therapy that focused on repairing the trauma of the original psychological injury, was the Freudian treatment of choice. However, psychoanalysis was costly and time-consuming and required lengthy training. Few could perform it. Thousands of patients in state institutions with severe mental illnesses were essentially ignored.

Freud's view of mental illness as a psychological disorder gained credibility. He was a prolific writer who reported that his patients improved through psychoanalysis and interpretation of dreams (Freud, 1900). His outcomes were not judged by contemporary standards or subjected to meta-analysis processes. Today, psychoanalysis remains as a treatment option for a select group of patients who have the cognitive abilities to discuss and understand complex psychological concepts.

National Action

During World War II (1939–1945), mental illness was beginning to be seen as a problem that could happen to anyone. Many “normal” people who volunteered for the armed services were disqualified on the grounds that they were psychologically unfit to serve. Others who had already served tours of duty developed psychiatric and emotional problems related to their wartime experiences. Today, these problems are recognized as a distinct disorder: posttraumatic stress disorder (see Chapter 29).

In 1946, the National Mental Health Act created a six-member National Mental Health Advisory Council that established the National Institute of Mental Health, which was responsible for overseeing and coordinating research and training. Under the Act’s provisions, the federal government also provided grants to states to support existing outpatient facilities and programs to establish new ones. Before 1948, more than half of all states had no clinics; by 1949, all but five had one or more. Six years later, there were 1,234 outpatient clinics. During the same time period, the Hill–Burton Act provided substantial federal support for hospital construction, which expanded the number of psychiatric units in general hospitals.

Impact of Psychopharmacology

Psychopharmacology revolutionized the treatment of people with mental illness. Initially, barbiturates, particularly amobarbital sodium (Amytal sodium), were tried for treating mental diseases in the 1930s (Malamud, 1944). When chlorpromazine was introduced in the 1950s, the mental health community was rather hopeful that a medication had been discovered to cure severe mental illness. In reality, the phenothiazines were the first of many antipsychotics to be developed (see [Chapter 12](#)). The medications calmed the patients and reduced some of the symptoms. With calmer patients and fewer symptoms, the negative effects of living in a restrictive and coercive institutional environment became evident.

A New National Objective: Community Treatment

In 1961, *Action for Mental Health*, a report of the Joint Commission on Mental Illness and Health Commission, called for larger investments in basic research; national personnel recruitment and training programs; one full-time clinic for every 50,000 individuals supplemented by general hospital units and state-run regional intensive psychiatric treatment centers; and access to emergency care and treatment in general, both in mental hospitals and in community clinics. The funding for the construction and operation of the community mental health system would be shared by federal, state, and local governments. The ideas expressed in the report clearly shifted authority for mental health programming to the federal government and were the basis of the federal legislation, the *Mental Retardation Facilities and Community Mental Health Centers Construction Act*, signed into law by John F. Kennedy in 1963. Unfortunately, this Act funded only some of the approaches proposed by the Commission and did not support the operation of state-run regional intensive psychiatric centers.

The supporters of this 1963 legislation believed the exact opposite of what Dorothea Dix believed during the previous century. That is, instead of viewing an institution as a peaceful asylum, institutionalization was viewed as contributing to the illness. If patients were moved into a “normal” community-living setting, it was believed that the symptoms of mental disorders could easily be treated and eventually would disappear. Thus, **deinstitutionalization**, the release of those confined to mental institutions for long periods of time into the community for treatment, support, and rehabilitation, became a national movement.

The inpatient state hospital population fell by about 15% between 1955 and 1965 and by about 59% during the succeeding decade. The 2,000 projected community mental health centers (CMHCs) that should have been in place by 1980 never materialized. By 1990, only about 1,300 programs provided various types of psychosocial rehabilitation services, such as vocational, educational, or social-recreational services (International Association of Psychosocial Rehabilitation, 1990).

Deinstitutionalization: A Failed Approach

There is no evidence that the majority of persons discharged from state hospitals benefited from CMHC services. The CMHCs, by and large, ignored the legions of people with serious mental illnesses and instead focused on the treatment of alcoholism and drug addiction. Individual psychotherapy, the primary treatment offered in most centers, was insufficient for those who needed other types of treatment, housing, and vocational opportunities. By the 1990s, deinstitutionalization was considered a failure.

CONTEMPORARY MENTAL HEALTH CARE

Millions of adults and children are disabled by mental illness every year. Compared with all other diseases, major depressive disorder, anxiety disorder, and opioid use disorders rank in the top eight conditions responsible for chronic disability in the United States from 1990 to 2016 (U.S. Burden of Disease Collaborators, 2018). Government initiatives are attempting to increase the public's understanding of mental disorders and related issues.

In 1999, *Mental Health: A Report of the Surgeon General* summarized evidence for the treatment of mental illness. As the first report addressing mental health by the Office of the Surgeon General, two main findings were presented (U.S. Department of Health and Human Services [U.S. DHHS], 1999):

- The efficacy of mental health treatments is well documented.
- A range of treatments exist for most mental disorders.

The following year, another landmark report, *Report of the Surgeon General's Conference on Children's Mental Health: A National Action Agenda*, was published. This report highlights consensus recommendations for identifying, recognizing, and referring children to services; increasing access to services for families; and using evidence for evaluating treatment services, systems of care, and financing (U.S. Public Health Service, 2000).

In 2003, the *President's New Freedom Commission on Mental Health* recommended that the mental health system be transformed. The report identified six goals as the foundation for transforming mental health care in the United States into a consumer-centered, family-centered, and recovery-oriented system ([Box 1.5](#)) (New Freedom Commission on Mental Health, 2003).

BOX 1.5

U.S. Goals in a Transformed Mental Health System

- Goal 1** Americans understand that mental health is essential to overall health.
- Goal 2** Mental health care is consumer and family driven.
- Goal 3** Disparities in mental health services are eliminated.
- Goal 4** Early mental health screening, assessment, and referral to services are common practices.
- Goal 5** Excellent mental health care is delivered, and research is accelerated.
- Goal 6** Technology is used to access mental health care and information.

New Freedom Commission on Mental Health. (2003). *Achieving the promise: Transforming mental healthcare in America* (p. 8). DHHS Publication No. SMA-03-3831. U.S. Department of Health and Human Services.

The *Mental Health Parity and Addiction Equity Act* was enacted in 2008 to ensure fairness between mental health and/or substance use disorder benefits and medical/surgical benefits covered by a health plan. The final rules were not effective until July 1, 2014, and implemented in 2015. Under this rule, a plan may not allow a patient to have unlimited visits with a medical provider and only a few visits to a mental health provider. In 2010, the *Patient Protection and Affordable Care Act* was passed that provided more people with access to affordable, effective treatments for their mental health needs. This law also prevents insurance companies from excluding people because of preexisting conditions. The intent of this legislation was to put the consumers of mental health care back in charge of their care. A study by the Commonwealth Fund in 2017 reported that access through Medicaid coverage and establishing state marketplaces improved access to care for millions of Americans, who, unlike those who remained uninsured, were less likely to experience delays or be unable to get care due to costs (Glied et al., 2017). A variety of provisions under the Affordable Care Act brought the biggest expansion of substance abuse services in a generation. It seemed the future of mental health care looked good, as legislation was propelling mental health care forward.

But today, the future does not look so promising. Advocacy groups are warning that despite growing demand for behavioral health services, rollbacks are coming. According to the National Alliance on Mental Illness, multiple bills proposed by the executive branch will weaken market placement protections (Palanker et al., 2020). The Cohen Veterans Network, a national not-for-profit philanthropic organization for veterans and their families, and the National

Council for Behavioral Health (2018) concluded that lack of access to care is fueling a mental health crisis, which is hitting rural and lower-income communities especially hard. The future of America's mental health services may hang in the balance of what advocates, consumers, and voters are able to accomplish in an unfriendly environment. This is a time in history to be ever vigilant of the gains previously made and to speak loudly on behalf of our mental health clients if we expect to keep them.

Recovery and the Consumer Movement

Recovery from mental illness is realistic and now a worldwide goal. Consumers are demanding that mental health services receive the same support and attention as other health services. The traditional medical model, which is viewed as autocratic and paternalistic, is being replaced by a collaborative model whereby mental health professionals work in partnership with consumers to help rebuild their lives. Consumer advocacy efforts have led to the implementation of recovery philosophy and practices (see [Chapter 2](#)). In this text, the terms *consumers* and *patients* are used interchangeably.

National Mental Health Objectives

The vision of (*Healthy People 2030*) is building a healthier future for all. The overarching goal of *Healthy People 2030* is to improve mental health based on the following objectives:

- General Mental Health and Mental Disorders
 - Increase the proportion of people with substance use and mental health disorders who get treatment for both.
 - Increase the proportion of primary care visits where adolescents and adults are screened for depression.
- Adolescents
 - Increase the proportion of adolescents with depression who get treatment.
 - Increase the proportion of children and adolescents with symptoms of trauma who get treatment.
 - Increase the number of children and adolescents with serious emotional disturbance who get treatment.
- Cancer
 - Increase quality of life for cancer survivors.

- Children
 - Increase the proportion of children and adolescents with attention deficit/hyperactivity disorder who get appropriate treatment.
 - Increase the proportion of children with mental health problems who get treatment.
 - Increase the proportion of children with autism spectrum disorder who receive special services by age 4 years.
 - Increase the proportion of children and adolescents who get appropriate treatment for anxiety or depression.
 - Increase the proportion of children and adolescents who get appropriate treatment for behavior problems.
 - Increase the proportion of children and adolescents who get preventive mental health care in school.
- Hospital and Emergency Services
 - Reduce emergency department visits related to nonmedical use of prescription opioids.
- Injury Prevention
 - Reduce the suicide rate.
 - Reduce the suicide attempts by adolescents.
- LGBT
 - Reduce suicidal thoughts in lesbian, gay, or bisexual high school students.
 - Reduce suicidal thoughts in transgender students.
- Parents or Caregivers
 - Reduce anxiety and depression in family caregivers of people with disabilities.
- People with Disabilities
 - Reduce the proportion of adults with disabilities who delay preventive care because of cost.
 - Reduce the proportion of adults with disabilities who experience serious psychological distress.
- Pregnancy and Childbirth
 - Increase the proportion of women who get screened for postpartum depression.
- Schools
 - Increase the proportion of public schools with a counselor, social worker, and psychologist.
- Violence Prevention
 - Reduce emergency department visits for nonfatal intentional self-harm injuries.

The mental health goal is to improve mental health through prevention and by ensuring access to appropriate, quality mental health services. Three new mental health issues have emerged in the past decade: physical and mental trauma experienced by military members and veterans, large-scale psychological trauma in communities caused by violence and natural disasters, and the understanding and treatment of older adults with dementia and mood disorders. Objectives focusing on mental health and mental disorders provide guidance for all health care professionals ([Box 1.6](#)).

BOX 1.6

Mental Health and Mental Disorders Objectives for the Year 2030

MENTAL HEALTH STATUS IMPROVEMENT

- Reduce the suicide rate.
- Reduce suicide attempts by adolescents.
- Reduce the proportion of adolescents who engage in disordered eating behaviors in an attempt to control their weight.
- Reduce the proportion of persons who experience major depressive episodes.

TREATMENT EXPANSION

- Increase the proportion of primary care facilities that provide mental health treatment onsite or by paid referral.
- Increase the proportion of children with mental health problems who receive treatment.
- Increase the proportion of juvenile residential facilities that screen admissions for mental health problems.
- Increase the proportion of persons with serious mental illness who are employed.
- Increase the proportion of adults with mental health disorders who receive treatment.
- Increase the proportion of persons with co-occurring substance abuse and mental disorders who receive treatment for both disorders.
- Increase depression screening by primary care providers.
- Increase the proportion of primary care physician office visits that screen youth ages 12 to 18 years for depression.
- Increase the proportion of homeless adults with mental health problems who receive mental health services.

Office of Disease Prevention and Health Promotion. 2021. *Healthy People 2030*. U.S. Department of Health and Human Services. Mental Health and Mental Disorders; Healthy People 2030. [health.gov](https://www.health.gov)

The challenge for psychiatric nursing is to work toward these goals through direct practice, advocating for persons with emotional and mental disorders, and improving the social and physical environments of care.

SUMMARY OF KEY POINTS

- Every practicing nurse cares for persons with an emotional or mental disorder. Every nurse needs basic psychiatric nursing knowledge and skills.

- Psychiatric–mental health nursing is a specialized area of nursing that promotes mental health through applying the nursing process. Psychiatric nurses care for people with a wide range of emotional problems and mental disorders.
- The need for psychiatric–mental health nursing was recognized near the end of the 19th century when Linda Richards opened the Boston City Hospital Training School for Nurses in 1882. Today, psychiatric nursing is recognized as one of the core mental health professions.
- Evidence-based practice is the standard of care in psychiatric nursing and in the mental health field. Historically, popular beliefs about the source of mental illnesses and treatment served as evidence.
- Over time, most treatment approaches, including institutionalization and deinstitutionalization, did not result in positive outcomes.
- Freud contributed to the psychoanalytic understanding of personality development and showed the strength of psychoanalysis. However, the psychoanalytic model was not effective in the treatment of people with severe mental illnesses.
- The U.S. Surgeon General’s reports, the President’s New Freedom Commission on Mental Health, and the goals of *Healthy People 2030* continue to highlight the need for resources for the care of persons with mental illness.
- The *Patient Protection and Affordable Care Act* prevents third-party payers from excluding people from insurance coverage for preexisting disorders.
- Today, consumers of mental health services insist on building partnerships with providers in order to recover from mental illness. The traditional medical model is being replaced by a collaborative approach in which consumers and mental health care providers develop a partnership in recovery-oriented care.

CRITICAL THINKING CHALLENGES

- l. Discuss whether these patients will have mental health needs:
 - a. A 32-year-old recently divorced woman with obesity and diabetes, who recently lost her job and can no longer pay for her medications.
 - b. A 25-year-old veteran whose war injuries have left him paralyzed from the waist down.
 - c. An 86-year-old woman whose husband recently died and now must move to a nursing home.
- l. Give three examples of changes in nursing practice based on new evidence.
- l. Present an argument for the moral treatment of people with mental disorders.
- l. Identify common themes in the 1999 *Mental Health: A Report of the Surgeon General*, the President's New Freedom Commission of Mental Health Report, and *Healthy People 2030: National Health Promotion and Disease Prevention Objectives*.

Movie Viewing Guides

One Flew over the Cuckoo's Nest: 1975. This classic film stars Jack Nicholson as Randle P. McMurphy, who takes on the state hospital establishment. This movie won all five of the top Academy Awards: Best Picture, Best Actor, Best Actress, Best Director, and Best Adapted Screenplay. The film depicts life in an inpatient psychiatric ward of the late 1960s and increased public awareness of the potential human rights violations inherent in a large, public mental system. However, the portrayal of electroconvulsive therapy is stereotyped and inaccurate, and the suicide of Billy appears to be simplistically linked to his domineering mother. This film depicts the loss of patients' rights and the use of coercion and punishment in mental institutions before the deinstitutionalization movement.

VIEWING POINTS: This film should be viewed from several different perspectives: What is the basis of McMurphy's admission? How does Nurse Ratchet interact with the patients? How are patient rights violated?

I Never Promised You a Rose Garden: This movie, now available on streaming services and DVD (Digital Video Disc), stars Kathleen Quinlan as Deborah

Blake, a 16-year-old young woman who is institutionalized for her mental illness. Her treatment in the institution was typical of the 1960s. In this film, the therapeutic relationship between Deborah and her physician was considered ideal.

VIEWING POINTS: How were patients, especially adolescent girls with emotional problems, treated in the 1960s? How would Deborah's treatment be judged today?

Mental Health and Mental Disorders

Fighting Stigma and Promoting Recovery

Mary Ann Boyd Rebecca Luebbert

KEYCONCEPTS

- mental disorders
- mental health
- recovery
- stigma

- trauma
- wellness

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Relate the concept of mental health to wellness.
2. Identify the rationale for promoting wellness for people with mental health challenges.
3. Differentiate the concepts of mental health and mental illness.
4. Discuss the significance of epidemiologic evidence in studying the occurrence of mental disorders.
5. Describe the consequences of the stigma of mental illness on individuals and families.
6. Identify recovery components and their role in the treatment of mental illness.
7. Discuss the role of trauma-informed care in recovery-oriented nursing practice.

KEY TERMS

- Cultural explanation
- Cultural idiom of distress
- Cultural syndrome
- Culture-bound syndromes
- *DSM-5*
- Epidemiology
- Incidence
- Label avoidance
- Point prevalence
- Prevalence
- Public stigma
- Rate
- Recovery-oriented care
- Self-stigma
- Syndrome
- Trauma-informed care

INTRODUCTION

To understand health and illness in any practice area, nurses need a basic understanding of mental health and its relationship with wellness. This chapter discusses concepts of mental health and wellness, the diagnosis of mental disorders, how the stigma of mental illness can be a barrier to treatment, and the importance of focusing on recovery from mental illness.

MENTAL HEALTH AND WELLNESS

Mental health is defined as a state of well-being in which the individual realizes their own abilities, can cope with life's normal stresses, can work productively and fruitfully, and can make a contribution to society. A person cannot be healthy without being *mentally* healthy, but it is possible to be mentally healthy and have a mental or physical disorder (World Health Organization [WHO], 2018). Mental health is essential to personal well-being, interpersonal relationships, and contributing to the community.

FIGURE 2-1: Eight dimensions of wellness. (Adapted from U.S. DHHS, SAMHSA. [2020b]. The eight dimensions of wellness.

<https://www.samhsa.gov/wellness-initiative/eight-dimensions-wellness>)

KEYCONCEPT **Mental health** is the emotional and psychological well-being of an individual who has the capacity to interact with others, deal with ordinary stress, and perceive one's surroundings realistically (adapted from American Nurses Association, American Psychiatric Nurses Association, & International Society of Psychiatric–Mental Health Nurses, 2014).

Mental health is an essential piece of total wellness. The concept of wellness encompasses both physical and mental health. Problems in one area impact the other area. Wellness is not the absence of disease or stress; it involves having a purpose in life, being actively involved in satisfying work and play, having joyful relationships, having a healthy body and living environment, and being happy. It includes the mental, emotional, physical, occupational, intellectual, and spiritual aspects of a person's life (U.S. Department of Health and Human Services, Substance Abuse & Mental Health Services Administration [U.S. DHHS, SAMHSA], 2020b) (see [Fig. 2.1](#)).

KEYCONCEPT Wellness is being in good physical and mental health. Improving physical health can benefit mental health, and vice versa. Wellness is not the absence of disease. There are eight dimensions of wellness: emotional, financial, social, spiritual, occupational, physical, intellectual, environmental (U.S. DHHS, SAMHSA, 2020b). See [Figure 2.1](#).

Mental health problems significantly impact the process of wellness. Individuals with mental health problems are more likely to die decades earlier than the general public from preventable diseases (Heiberg et al., 2018). People with serious mental health problems often face social, economic, and/or environmental disadvantages that result in lack of access to health care, lack of information, and lack of culturally and linguistically competent care and programs (U.S. DHHS, SAMHSA, 2020c).

OVERVIEW OF MENTAL HEALTH DISORDERS

Mental disorders can disrupt mental health and result in one of the most common causes of disability. In this text, the terms *mental disorder* and *mental illness* will be used interchangeably.

KEYCONCEPT Mental disorders are clinically significant disturbances in cognition, emotion regulation, or behavior that reflect a dysfunction in the psychological, biologic, or developmental processes underlying mental dysfunction. They are usually associated with distress or impaired functioning (American Psychiatric Association [APA], 2013).

A mental illness or mental disorder is a **syndrome**, a set of symptoms that cluster together that may have multiple causes and may represent several different disease states that have not yet been defined. Unlike many medical

diseases, mental disorders are defined by clusters of behaviors, thoughts, and feelings, not by underlying biologic pathology. Laboratory tests are not generally used in diagnosing mental disorders.

The landmark study *Global Burden of Disease 2010* found an alarming impact of mental and behavioral disorders on health and productivity in the world. Depression is one of the leading disease burdens in middle- and high-income countries such as the United States. In 2019, in the United States, 1 in 5 adults, or 47.6 million people, had a mental illness (National Institute of Mental Health [NIMH], 2019).

Evidence for this very high occurrence of mental disorders is established through epidemiologic research. **Epidemiology**, the study of patterns of disease distribution and determinants of health within populations, contributes to the overall understanding of the mental health status of population groups, or aggregates, and associated factors. Epidemiologic studies examine associations among possible factors related to an area of investigation, but they do not determine causes of illnesses. The Centers for Disease Control and Prevention (CDC) tracks and reports mental health epidemiologic data. Throughout this book, epidemiologic data are included in discussions of mental health problems and mental disorders. See [Box 2.1](#) for an explanation of terms.

BOX 2.1

Epidemiologic Terms

In epidemiology, certain terms have specific meanings relative to what they measure. When expressing the number of cases of a disorder, population rates, rather than raw numbers, are used.

Rate is the proportion of the cases in the population when compared with the total population. It is expressed as a fraction, in which the numerator is the number of cases and the denominator is the total number in the population, including the cases and non-cases. The term *average rate* is used for measures that involve rates over specified time periods:

$$\text{Rate} = \frac{\text{Case in population}}{\text{Total population (cases and non-cases)}}$$

Prevalence refers to the total number of people who have the disorder within a given population at a specified time regardless of how long ago the disorder started.

Point prevalence is a basic measure that refers to the proportion of individuals in the population who have the disorder at a specified point in time (*t*). This point can be a day on the calendar, such as April 1, 2020, or a point defined in relation to the study assessment, such as the day of the interview. This is also expressed as a fraction:

$$\text{Point prevalence rate} = \frac{\text{Cases at } t}{\text{Population at } t}$$

Incidence refers to a rate that includes only *new* cases that have occurred within a clearly defined time period. The most common time period evaluated is 1 year. A study of incidence cases is more difficult than a study of prevalent cases because a study of incidence cases requires at least two measurements to be taken: one at the start of the prescribed time period and another at the end of it.

Diagnosis of Mental Health Conditions

Mental disorders are organized and diagnosed according to the criteria published in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5; APA, 2013). The current **DSM-5** system contains subtypes and other specifiers that further classify disorders. Although the *DSM-5* specifies criteria for diagnosing mental disorders, there are no absolute boundaries separating one disorder from another, and disorders often have different manifestations at different points in time.

In a mental disorder, alterations in behaviors, thoughts, and feelings are unexpected and are outside normal, culturally defined limits. If a behavior is considered normal within a specific culture, it is not viewed as a psychiatric symptom. For example, members of some religious groups “speak in tongues.” To an observer, it appears that the individuals are hallucinating (see [Chapter 24](#)), but this behavior is normal for this group within a particular setting.

The amount of disability or impairment in functioning is an important consideration when assessing a person with a mental disorder. A person’s ability to understand, communicate, and get along with others is important in the recovery process. If symptoms impair an individual’s ability to independently perform self-care and daily activities, recovery will be more difficult. The World Health Organization’s Disability Assessment Schedule 2.0 is an instrument that can be used for measuring the amount of impairment that the individual experiences.

BOX 2.2

Frequently Reported Cultural Syndromes and Idioms

Ataque de nervios: frequent episodes of loss of control, uncontrollable crying, tremors, and severe anxiety and sadness with somatization symptoms including muscle ache and headache, nausea, loss of

appetite, insomnia, fatigue, and psychomotor agitation. Reported among women over 45 years old, with little education and who have experienced a loss (such as a divorce) or acute distress.

Susto: fright characterized by symptoms of psychomotor agitation, anorexia, insomnia, fever, diarrhea, confusion, apathy, depression, and introversion following an emotional trauma or witnessing a traumatic experience.

Adapted from Durá-Vilá, G., & Hodes, M. (2012). Cross-cultural study of idioms of distress among Spanish nationals and Hispanic American migrants: *susto*, *nervios* and *ataque de nervios*. *Social Psychiatry and Psychiatric Epidemiology*, 47(10), 1627–1637.

Culture-bound syndromes, which are illnesses that occur only within a specific culture, have been studied for years. The *DSM-5* replaced the term with three concepts: **Cultural syndrome** is a group of co-occurring symptoms that occurs in one culture, for example, *ataque de nervios*. **Cultural idiom of distress** is a phrase or way of talking about distress within a culture, for example, *susto*. **Cultural explanation** or cause is an etiology that is culturally conceived (APA, 2013). There is little research that reliably describes cultural syndromes or idioms of distress, but there are two conditions—*ataque de nervios* and *susto*—that are frequently reported in a small number of persons (Durá-Vilá & Hodes, 2012) ([Box 2.2](#)).

Stigma

Stigma is one of the major barriers to treatment, recovery, and social integration. A major reason individuals with mental health problems do not seek or continue with treatment is the stigma they encounter. Stigma, myths, and misconceptions surrounding mental illness contribute to the discrimination and human rights violations experienced by people living with mental illness.

KEYCONCEPT Stigma is a dynamic social/interactional process in which the stigmatized person is labeled as different and linked to negative stereotypes. Persons with stigmatizing beliefs socially distance themselves from the stigmatized person. Public stigma, self-stigma, and label avoidance are three types of stigma people with mental illnesses experience.

Public Stigma

Public stigma occurs after individuals are publicly “marked” as having a mental

illness. When they act or say things that are odd or unusual or tell others that they have a mental illness, these individuals are at risk of being subjected to prejudice and discrimination. Common stereotypes include being dangerous, unpredictable, and incapable of functioning independently. People with mental illness are sometimes treated as if they are responsible for their disabilities and are inaccurately accused of being weak or immoral (Corrigan & Al-Khouja, 2018). Stigmatization robs individuals of work, independent living, and meaningful relationships.

When people with mental illnesses or emotional problems are stigmatized by society, they are often ostracized by the society in which they live. The stigma associated with all forms of mental illness is strong but generally increases the more an individual's behavior differs from the cultural norm. Reducing stigma has been identified as a public health priority (National Academy of Sciences, 2016).

Media perpetuates the stigma of mental disorders and treatment. News coverage often associates violence with mental illness (McGinty et al., 2018). Few describe successful treatment or recovery. Additionally, mental health treatment and providers are often stigmatized (Henderson, 2018). In films, psychiatric hospitals are often portrayed as dangerous and unwelcoming places, as in *The Snake Pit* (1948), *One Flew Over the Cuckoo's Nest* (1975), *Instinct* (1999), *Twelve Monkeys* (1995), *Sling Blade* (1996), *Girl, Interrupted* (1999), *Don Juan Demarco* (1994), *A Beautiful Mind* (2001), and *Analyze That* (2002). Nurses are dressed in white in contrast to the dark, gloomy surroundings, and patients have little to do other than to walk the halls of the institution, acting odd.

One of the best ways to counteract the negative effects of stigma is to have contact with the stigmatized group (Corrigan & Al-Khouja, 2018). Another way is to use non-stigmatizing language. Just as a person with diabetes mellitus should not be referred to as a "diabetic" but rather as a "person with diabetes," a person with a mental disorder should never be referred to as a "schizophrenic" or "bipolar" but rather as a "person with schizophrenia" or a "person with bipolar disorder." Using words such as *psycho*, *nuts*, *funny farm*, and *maniac* reinforces negative images of mental illness. Jokes that depict people with mental illness as stupid, dangerous, or incompetent perpetuate negative myths.

Self-Stigma

Self-stigma occurs when negative stereotypes are internalized by people with mental illness. Patients are aware of the public's negative view of mental illness and agree with the public's perceptions. As they become aware of the negative stereotypes, they begin agreeing with the stereotype. Then they may begin applying the stigma to themselves: "I have a mental illness, so I must be incompetent." As a result of the application of the negative stereotype to self, they develop low self-esteem (Corrigan & Nieweglowski, 2019).

Label Avoidance

Label avoidance, avoiding treatment or care in order not to be labeled as being mentally ill, is another type of stigma and one of the reasons that so few people with mental health problems actually receive help. By avoiding treatment, they avoid the stigma of mental illness. For example, negative views of mental illness by several of the Asian cultures influence the willingness of their members to seek treatment. They may ignore their symptoms or refuse to seek treatment because of the stigma associated with being mentally ill (Corrigan & Nieweglowski, 2019).

RECOVERY FROM MENTAL ILLNESS

Recovery is the single most important goal for individuals with mental disorders. The following definition of recovery was released following a lengthy consensus-seeking process that began in 2010 and involved government agency officials, experts, consumers, family members, advocates, researchers, managed care representatives, and others.

KEYCONCEPT **Recovery** from mental disorders and/or substance use disorders is a process of change through which individuals improve their health and wellness, live a self-directed life, and strive to reach their full potential (U.S. DHHS, SAMHSA, 2020a).

Recovery-oriented treatment is based on the belief that mental illnesses and

emotional disturbances are treatable and that recovery is an expectation. There are four dimensions that support recovery: *health* (managing disease and living in a physically and emotionally healthy way), *home* (a safe and stable place to live), *purpose* (meaningful daily activities and independence, resources, and income), and *community* (relationships and social networks) (U.S. DHHS, SAMHSA, 2020a). Consumers and families have real and meaningful choices about treatment options and providers. In **recovery-oriented care**, the person with a mental health problem develops a partnership with a clinician to manage the illness, strengthen coping abilities, and build resilience for life's challenges (Box 2.3).

Mental health recovery benefits not only the individual and family but also society by ultimately reducing the global burden of mental health problems. Recovery is guided by 10 fundamental principles. (Box 2.4). See Chapter 9 for further discussion of recovery.

BOX 2.3

Cultural Change: Implementation of a Recovery Program

McDonagh, J. G., Haren, W. B., Valvano, M., Grubaugh, A. L., Wainwright, F. C., Rhue, C. H., Pelic, C. M., Pelic, C. G., Koval, R., & York, J. A. (2019). Cultural change: Implementation of a recovery program in a Veterans Health Administration Medical Center inpatient unit. *Journal of the American Psychiatric Nurses Association*, 25(3), 208–217.

THE QUESTION: How does an inpatient mental health unit implement recovery-oriented services?

METHODS: A recovery-oriented inpatient program on a 24-bed locked unit consisted of several critical components, including the development of an interprofessional committee, creation of vision and mission statement, education of staff, integration of the peer support specialist role, development and delivery of recovery-oriented curriculum, development of the interprofessional program partnership, and adoption of the Veteran's Recovery Self-Help Resource Book and the Veterans Recovery Worksheet. An interprofessional Partnership for Wellness conducted evidence-based recovery and holistic health programs for 4 to 6 hours per day. The measurement indicators included veteran feedback, program requirements, and system measures.

FINDINGS: Preliminary indicators over a 2-year period suggest that the veterans rated group content and relevance high, per-post psychiatric rehospitalization rates decreased by 46%, and fidelity to the recommended strategies was high.

IMPLICATIONS FOR NURSING: Recovery-oriented practice is realistic in an inpatient mental health unit if there are committed interprofessional staff, effective training, and an organizational culture exemplifying recovery-oriented principles.

Recovery-Oriented Care and Trauma-Informed Care

Mental health professionals increasingly focus on the harmful effects of trauma on health and mental health status. Individuals who experience trauma, particularly in childhood, have a higher incidence of chronic disease and behavior health issues. Trauma is a universal experience for people with mental and substance abuse disorders, and addressing it is a critical component of mental health care (U.S. DHHS, SAMHSA, 2014).

KEYCONCEPT Individual **trauma** results from an event, a series of events, or a set of circumstances that is experienced by an individual as physically or emotionally harmful or life threatening and that has lasting adverse effects on the individual's functioning and mental, physical, social, emotional, or spiritual well-being (U.S. DHHS, SAMHSA, 2014).

BOX 2.4

Guiding Principles of Recovery

Recovery emerges from hope: The belief that recovery is real provides the essential and motivating message of a better future—that people can and do overcome the internal and external challenges, barriers, and obstacles that confront them.

Recovery is person driven: Self-determination and self-direction are the foundations for recovery, as individuals define their own life goals and design their unique path(s).

Recovery occurs via many pathways: Individuals are unique with distinct needs, strengths, preferences, goals, culture, and backgrounds, including trauma experiences that affect and determine their pathway(s) to recovery. Abstinence is the safest approach for those with substance use disorders.

Recovery is holistic: Recovery encompasses an individual's whole life, including mind, body, spirit, and community. The array of services and supports available should be integrated and coordinated.

Recovery is supported by peers and allies: Mutual support and mutual aid groups, including the sharing of experiential knowledge and skills, as well as social learning, play an invaluable role in recovery.

Recovery is supported through relationship and social networks: An important factor in the recovery process is the presence and involvement of people who believe in the person's ability to recover; who offer hope, support, and encouragement; and who also suggest strategies and resources for change.

Recovery is culturally based and influenced: Culture and cultural background in all of its diverse representations including values, traditions, and beliefs are key in determining a person's journey and unique pathway to recovery.

Recovery is supported by addressing trauma: Services and supports should be trauma informed to foster

safety (physical and emotional) and trust as well as to promote choice, empowerment, and collaboration.

Recovery involves individual, family, and community strengths and responsibility: Individuals, families, and communities have strengths and resources that serve as a foundation for recovery.

Recovery is based on respect: Community, systems, and societal acceptance and appreciation for people affected by mental health and substance use problems—including protecting their rights and eliminating discrimination—are crucial in achieving recovery.

From U.S. DHHS, SAMHSA. (2020a). Recovery and recovery support. <https://www.samhsa.gov/find-help/recovery>.

An important aspect of recovery-oriented care is preventing re-traumatization by exposing individuals to triggers—such as confinement to a mental health unit or applying restraints—only when accompanied by the proper support and sensitivity (National Council for Behavioral Health, 2020). **Trauma-informed care** is integral to recovery-oriented nursing care for people with emotional problems and mental disorders. Trauma-informed care incorporates a basic realization and understanding of the impact of trauma on individuals, families, groups, organizations, and communities. In trauma-informed care, nurses recognize the signs of trauma and respond by fully integrating knowledge about the trauma into policies, procedures, and practice.

Individuals with mental illnesses can regain mental health with the support of families, mental health providers, and society. The contributions of these individuals strengthen communities and support the overall health of a nation.

SUMMARY OF KEY POINTS

- Mental health is the emotional and psychological well-being of an individual. To be mentally healthy means that one can interact with others, deal with daily stress, and perceive the world realistically. Mental disorders are health conditions characterized by alterations in thinking, mood, or behavior and are associated with distress or impaired functioning.
- Good physical and mental health characterize wellness. Individuals can have a mental disorder and experience wellness.
- Epidemiology is important to understanding the distribution of mental illness and determinants of health within a given population. The rate of occurrence

refers to the proportion of the population that has the disorder. Incidence is the rate of new cases within a specified time. Prevalence is the rate of occurrence of all cases at a particular point in time.

- Stigma toward mental illness can be viewed in three ways. Public stigma marks a person as having a mental illness. When a person with a mental illness shares the public's negative view of mental illness, self-stigma occurs. If a person with a mental illness does not seek treatment because of fear of being labeled "mentally ill," label avoidance occurs.
- The *DSM-5* organizes psychiatric diagnoses according to behaviors and symptom patterns.
- Cultural syndromes are specific disorders found within a particular culture. There is little research on the syndromes, but *ataque de nervios* and *susto* are well documented.
- Mental health recovery is the single most important goal for the mental health delivery system. Recovery is viewed a process of changes through which individuals improve their health and wellness, live a self-directed life, and strive to reach their full potential.
- Trauma is experienced by many individuals as physically or emotionally harmful or life threatening and has lasting adverse effects on the individual. Trauma-informed care is integral to recovery-oriented care.

CRITICAL THINKING CHALLENGES

1. A person who is seeking help for a mental disorder asks why the individual's physical health is important to the nurse.
2. Compare the meaning of the epidemiologic terms *prevalence*, *incidence*, and *rate*. Access the CDC's website (www.cdc.gov) and identify major mental health problems in the United States.
3. Examine the description of people with mental illness in the media, including television programs, news, and newspapers. Are negative connotations evident?
4. Examine how family and friends describe people with mental illness. Do you think their description of mental illness is based on fact or myth? Explain.
5. Explain the three forms of stigma and give examples.

5. Discuss the negative impact of labeling someone with a psychiatric diagnosis.
7. Using the components of mental health recovery as a framework, compare the goals for a person with schizophrenia with the goals for a person with a medical disease such as diabetes.
8. Discuss the application of trauma-informed care with a person who has experienced a trauma such as rape or a life-threatening event.

To Write Love On Her Arms (2015). This 2015 Substance Abuse and Mental Health Services Administration Voice Award winner is a true story that presents a vision of hope, healing, and redemption. Renee, played by Kat Dennings, is a Florida girl living with addiction and mental illness. She has also experienced abuse and is trying to come to grips with that trauma. Renee discovers the value of friendships and courageously embarks on a daunting journey toward recovery.

VIEWING POINTS: Observe the stigma that is associated with having a mental illness. Identify the trauma Renee experienced and how it influences her ability to engage in treatment.

Unfolding Patient Stories: Sandra Littlefield

Part 1

Sandra Littlefield is a 36-year-old female with borderline personality disorder. Her history includes several divorces, drug and alcohol abuse, poor impulse control, anxiety, cutting, suicide attempts, prostitution, and jail time. Why could she be subject to stereotypes and bias? Describe the stigma of mental illness and how it can affect her as an inmate, in the community, and with recovery? What actions by Sandra may be influenced by internalizing the perceived stigma people have of her?

Cultural and Spiritual Issues Related to Mental Health Care

Mary Ann Boyd

KEYCONCEPTS

- cultural competence
- culture
- spirituality

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Discuss the ways that cultural competence is demonstrated in psychiatric–mental health nursing.
2. Describe the beliefs about mental health and illness in different cultural and social groups.
3. Differentiate concepts of religiousness and spirituality.
4. Discuss the role of spirituality and religiousness in persons with mental illness.
5. Discuss the beliefs of major religions and their role in shaping views on mental illnesses.

KEY TERMS

- Acculturation
- Cultural explanations
- Cultural identity
- Cultural idiom of distress
- Health literacy
- Linguistic competence
- Religiousness

INTRODUCTION

All cultural groups have sets of values, beliefs, and patterns of accepted behavior, and it is often difficult for those of one culture to understand those of another. This is especially true regarding mental illness—whereas some cultures view it as a condition for which the ill person must be punished and ostracized from society; other cultures are more tolerant and believe that family and community members are key to the care and treatment of mentally ill people. Nurses' and patients' religious backgrounds and cultural heritages may be different, so it is important for nurses to clearly understand the thinking and perspectives of other cultures and groups.

This chapter examines cultural and social mores of various cultural and religious groups. Understanding cultural and religious beliefs and the significance of spirituality is especially important when caring for people with mental health problems. These beliefs and practices can define and shape the experience of being mentally ill and influence the willingness to seek care.

Treating mental disorders is intertwined with people's attitudes about themselves, their beliefs, values, and ways.

KEYCONCEPT Culture is not only a way of life for people who identify or associate with one another on the basis of some common purpose, need, or similarity of background but also the totality of learned, socially transmitted beliefs, values, and behaviors that emerge from its members' interpersonal transactions that can be used to define them as a collective. Culture is a term that goes beyond just race or ethnicity. It can also refer to such characteristics as age, gender, sexual orientation, disability, religion, income level, education, geographical location, or profession.

Cultures are dynamic and continually changing. When immigrants arrive in the United States with their own cultures, they begin to adapt to their new environment. **Acculturation** is the term used to describe the socialization process by which underrepresented groups learn and adopt selective aspects of the dominant culture. Their culture changes because of the influences of the new environment. Eventually, a new minority culture evolves that is different than the native culture and different from the dominant culture, which in turn is transformed by the new residents.

Everyone has a **cultural identity** or a set of cultural beliefs with which one looks for standards of behavior. Because culture is broadly defined, many people consider themselves to have multiple cultural identities. Often, the nurse is challenged to provide culturally appropriate care for persons from cultures other than the nurse's culture. Uncertainty about cultural beliefs and practices can result in feelings of anxiety and vulnerability when interacting with patients from other cultures. Patients may interpret the nurse's anxiety as a lack of caring or competence. It is important to learn and understand each patient's cultural background and identity to provide culturally competent care and avoid miscommunication and knowledge barriers (Markey & Okantey, 2019).

CULTURAL AND LINGUISTIC COMPETENCE

Cultural and linguistic competence is especially important for psychiatric-mental health nurses because of the significance of therapeutic communication. There are several definitions of cultural and linguistic competence, but there is a consensus that cultural and linguistic competence involves an adjustment or recognition of one's own culture to understand the culture of another person.

Linguistic competence, the capacity to communicate effectively and convey

information that is easily understood by diverse audiences, is an important part of cultural competence (Harris-Haywood et al., 2014). Linguistic competence not only refers to the appropriate use of words, grammar, and syntax, but also to the practical aspects such as choice of discussion topics, taking turns, use of metaphors, and the “hidden rules” of interactions. The following is an example of a hidden rule: For one patient, it is a cultural expectation for a nurse to sit down and “chit chat” before providing care; for another patient, limited eye contact is best. A nurse who is culturally competent understands and appreciates cultural differences in health care practices and similarities within, among, and between groups.

KEYCONCEPT **Cultural competence**, the ability to interact effectively with people of different cultures, involves a set of academic and interpersonal skills that are respectful of and responsive to the health beliefs, health care practices, and cultural and linguistic needs of diverse patients to bring about positive health care outcomes (U.S. Department of Health and Human Services [U.S. DHHS], 2020; Substance Abuse and Mental Health Services Administration, 2014).

Cultural competence can reinforce a person’s engagement in treatment, therapeutic relations, and treatment outcomes. It is essential in decreasing disparities in mental health services. There are linguistic variations within cultural groups as well as cultural variations within a language group. Speaking the same language does not guarantee shared meaning and understanding. Communication may be adversely affected when patients are unable to fully express themselves in English. Understanding the impact of literacy levels is integral to providing culturally competent care. Demonstrating an understanding that literacy levels contribute to the interpretation of personal, psychological experiences is critical.

The ability to obtain, process, and understand basic health information and services in order to make health decisions is dependent upon a person’s **health literacy**, that is, the ability to use reading, writing, verbal, and numerical skills in the context of health (Agency for Healthcare Research & Quality [AHRQ], 2018). If a person has limited health literacy and cannot process and understand basic health information and services, it is unlikely the individual will be able to follow discharge instruction, take prescribed medication, and adhere to a treatment plan (Glick et al., 2019; Polster, 2018).(See [Box 3.1](#).)

BOX 3.1

Health Literacy Universal Precautions

- Health professionals should assume that all patients and caregivers may have difficulty comprehending health information.
- Health professionals should communicate in ways that anyone can understand.
- Health literacy universal precautions are aimed at the following:
 - Simplifying communication with and confirming comprehension for all patients, so that the risk of miscommunication is minimized.
 - Making the office environment and health care system easier to navigate.
 - Supporting patient's efforts to improve their health.
- Four domains are important for promoting health literacy.
 - Spoken communication
 - Written communication
 - Self-management and empowerment
 - Supportive systems

Agency for Healthcare Research & Quality. (2018). *Health literacy universal precautions toolkit* (2nd ed.). Agency for Healthcare Research and Quality. <https://www.ahrq.gov/health-literacy/quality-resources/tools/literacy-toolkit/healthlittoolkit2-intro.html>

CULTURAL AND SOCIAL FACTORS AND BELIEFS ABOUT MENTAL ILLNESS

Cultural beliefs and practices influence how patients communicate and manifest their symptoms, cope with their illnesses, and receive family and community support. The *DSM-5* differentiates **cultural idiom of distress**, a commonly used term or phrase that describes the suffering within a cultural group from **cultural explanations**, perceived causes for symptoms (American Psychiatric Association [APA], 2013). For example, the term *nervios* is an idiom used by Hispanics in the Western Hemisphere that explains a wide range of somatic and emotional symptoms such as headache, irritability, nervousness, insomnia, and difficulty concentrating. The term *susto* (extreme fright causing the soul to leave the body) is believed to be the cause of a group of varied symptoms including appetite disturbance, sleep problems, and low self-worth among people in Central and South America. See [Chapter 2](#).

Social factors contribute to the development of mental disorders. Ethnic and racial minorities in the United States live in a social environment of inequality that increases their exposure to racism, discrimination, violence, and poverty,

which contribute to the experience of their illnesses (Hauenstein et al., 2019). Racially and ethnically diverse groups are less likely to receive mental health services and more likely to receive poorer quality care. Poverty is found in all cultural groups and is present in other groups, such as older adults, people with physical disabilities, individuals with psychiatric impairments, and single-parent families. In the United States in 2019, 22.2% of people living below the poverty line are single mothers and their children; 26.4% of Blacks live below the poverty level, as do 20.9% of Hispanic Americans and 12.3% of Whites. Currently in the United States, the poverty guidelines for a family of four is a yearly income of \$26,200 or less in the 48 mainland states; \$32,750 or less in Alaska; and \$30,130 or less in Hawaii (U.S. DHHS, 2020). These figures do not include the financial impact of the coronavirus pandemic.

Families living in poverty are under tremendous financial and emotional stress, which may trigger or exacerbate mental problems. Along with the daily stressors of trying to provide food and shelter for themselves and their families, their lack of time, energy, and money prevents them from attending to their psychological needs. Often, these families become trapped in a downward economic spiral as tension and stress mount. The inability to gain employment and the lack of financial independence only add to the feelings of powerlessness and low self-esteem. Being self-supporting gives one a feeling of control over life and bolsters self-esteem. Dependence on others or the government causes frustration, anger, apathy, and feelings of depression and meaninglessness. Alcoholism, depression, and child and partner abuse may become a means of coping with such hopelessness and despair. The homeless population is the group most at risk for being unable to escape this spiral of poverty.

Hispanic Americans

The number of Hispanic or Latinx Americans living in the United States has been gradually increasing, and this group is now the largest underrepresented in the United States, constituting 59 million (18.3% of the total population). Countries of origin include Mexico (62%), Central and South American (15%), Puerto Rico (10%), and Cuba (4%). Hispanic populations are largest in urban areas, such as New York, Chicago, Los Angeles, San Francisco, and Miami–Fort Lauderdale (U.S. Census Bureau, 2018).

Studies indicate that Hispanic Americans tend to use all other resources before

seeking help from mental health professionals. They are more likely to seek help at nonprofit hospitals or community health centers that also offer mental health services. Reasons for this are unclear, but barriers for treatment include beliefs that mental health facilities do not accommodate their cultural needs (e.g., language, beliefs, values), cost of care, availability of services, accessibility of services, and concerns regarding immigration status (Rosales & Calvo, 2019; Stafford & Draucker, 2020).

Black and African Americans

In 2018, the estimated population of Black or African Americans was 47.8 million or 13.4% of the U.S. population (U.S. Census Bureau, 2020). Although Black Americans share many beliefs, attitudes, values, and behaviors, there are also many subcultural and individual differences based on social class, country of origin, occupation, religion, educational level, and geographic location. African Americans have extensive family networks in which members can be relied on for moral support, help with child rearing, financial aid, and help in crises. Older family members are treated with great respect. But Blacks with mental illness suffer from the stresses of double stigma—not only from their own cultural group but also from longtime racial discrimination. To make matters worse, racial discrimination may come from within the health community itself (Box 3.2).

Several studies show that diagnoses and treatment for African Americans often are racially biased. African Americans are disproportionately diagnosed as having schizophrenia when compared to other groups. This disparity in diagnosis in schizophrenia has been stable over the past 3 decades. There is some indication that using a structured interview (rather than a subjective clinical interview) may reduce this disparity (Schwartz et al., 2019).

BOX 3.2

Barriers and Facilitators to Mental Health Help-Seeking among African American Youth and Their Families: A Systematic Review Study.

Planey, A. M., Smith, S. M., Moore, S., & Walker, T. D. (2019). Barriers and facilitators to mental health help-seeking among African American youth and their families: A systematic review study. Children &

THE QUESTIONS: 1. What are the barriers to African American youth mental health help-seeking outpatient mental health service use? 2. What are the facilitators of African American youth mental health help-seeking outpatient mental health service use?

METHODS: A systematic approach was used to retrieve relevant research studies related to barriers to and facilitators of mental health service use among Black/African American youth. Articles published between 2000 and 2017 were selected from electronic databases (CINAHL, PsychINFO, and SocINDEX) using keywords that covered the following domains: race, child, mental health, use, and barrier/facilitator. Only empirical qualitative, quantitative, and mixed methods studies were included.

Fifteen articles met study criteria. Six used quantitative methods, eight used qualitative methods, and one used a mixed methods approach. Six studies were reported by the youth, six were reported by parents/caregivers, and two were from gatekeepers (teachers, clinicians). One provided data from youth and caregiver.

FINDINGS: Seven themes identified barriers of mental health help-seeking and service use. (1) Child-related factors included beliefs that the child does not have a mental health problem or the problem is not serious; beliefs that youth should be self-reliant and handle their own problems, and child or youth refused to attend mental health treatment. (2) Clinician-therapeutic barriers included negative prior experiences with mental health care, perceptions that treatments were not effective, lack of trust of the provider, and fear of negative consequences of seeking and using mental health care services. (3) Stigma and shame included fears that friends would laugh, joke, or tease them or that family members might feel offended because they were not able to help and the fear of the caregivers that would find out or what would others think about them. (4) The ideals and values of faith communities were a barrier as well as the lack of information about mental illness shared by religious leaders. (5) Mental health care was not affordable, available, and accessible to many youths. (6) School systems were identified as a barrier by both parents and teachers. Teachers found it difficult to communicate with the parents; parents perceived the school and teachers as part of the problem.

Seven themes identified facilitators of mental health help-seeking and service use. They include severity of child mental health, the caregiver experiences and commitment, a supportive social network, therapeutic factors (positive therapeutic relations), religion and spirituality, referrals and mandates by parents and gatekeepers, and geographic region. (Residence in urban area had more access.)

IMPLICATIONS FOR NURSING: The nurse should recognize that the use of mental health services by African American children and youth involves many barriers and facilitators. In one situation, the school system is a barrier and in another, a facilitator. The children and youth face difficult challenges in accessing quality mental health care. Nurses can identify facilitators and support the caregiver's access to services.

Asian Americans, Polynesians, and Pacific Islanders

In 2018 more than 22.2 million (5.9% of the U.S. population) Asian Americans, Polynesians, and Pacific Islanders lived in the United States, and this group represents one of the fastest growing underrepresented populations in the United States. This large multicultural group includes Chinese, Filipino, Japanese, Asian Indian, Korean, Vietnamese, Laotian, Cambodian, Hawaiian, Samoan, and Guamanian people. Most Chinese, Japanese, Korean, Asian Indian, and Filipino immigrants have migrated to urban areas; the Vietnamese have settled throughout the United States (U.S. Census Bureau, 2020).

Generally, Asian cultures have a tradition of denying or disguising the existence of mental illnesses. In many of these cultures, it is an embarrassment to have a family member treated for mental illness, which may explain the extremely low utilization of mental health services (Chu et al., 2021).

Asian Americans may experience a culture-bound syndrome, such as neurasthenia, which is characterized by fatigue, weakness, poor concentration, memory loss, irritability, aches and pains, and sleep disturbances. Associated with the Korean culture, *hwa-byung*, “suppressed anger syndrome,” is characterized by subjective and expressed anger, sensations of heat, and feelings of hate (Im et al., 2017). Research regarding specific mental health problems in Asian cultures is sparse, but various data suggest that rates of suicide within American Indian/Alaska Native adolescents are higher than those of other adolescents in the United States (American Foundation for Suicide Prevention, 2020).

Native Americans

In 2016, the estimated population of Native Americans was more than 6.9 million people, 1.3% of the U.S. population (U.S. Census Bureau, 2018). Native American cultures emphasize respect and reverence for the earth and nature, from which come survival and comprehension of life and one’s relationships with a separate, higher spiritual being and with other human beings. Shamans, or medicine men, are central to most cultures. They are healers believed to possess psychic abilities. Healing treatments rely on herbal medicines and healing ceremonies and feasts. Self-understanding derives from observing nature; relationships with others emphasize interdependence and sharing.

Traditional views about mental illnesses vary among the tribes. In some, mental illness is viewed as a supernatural possession, as being out of balance

with nature. In certain Native American groups, people with mental illnesses are stigmatized. However, the degree of stigmatization is not the same for all disorders. In tribal groups that make little distinction between physical and mental illnesses, there is little stigma. In other groups, an event, such as suicide, is stigmatized. Different illnesses may be encountered in different Native American cultures and gene pools.

Arab Americans

The Arab American community includes immigrants and their descendants from several Arab world countries including Syria, Lebanon, Egypt, Palestine, Iraq, Jordan, and Yemen. There are an estimated 3.7 million Arab Americans in the United States with two-third living in ten states (California, Michigan, New York, Florida, Texas, New Jersey, Illinois, Ohio, Pennsylvania, and Virginia.) More than one-third live in Los Angeles, Detroit, and New York. More than 82% are U.S. citizens. Arab Americans have a strong commitment to family, economic and educational achievements, and making contributions to all aspects of American life. The first wave of Arab immigrants that came to the United States during the 19th and 20th centuries were primarily Christian. Since the 1960s, Muslim Arabs began immigrating in greater numbers to the United States. Most Arab Americans in the United States practice Christianity (Arab American Institute Foundation, 2020).

Mental illness and seeking mental health care are highly stigmatized in all Arab countries. Although there is little research about the views of Arab Americans, there is emerging evidence that stigma toward mental health treatment is preventing individuals from accessing treatment. They are more likely to visit a primary care provider with somatic problems that represent a mental health problem (Dallo et al., 2018; Dardas & Simmons, 2015; Jaber et al., 2015). An additional stressor is discrimination against the Muslim Arab American community, particularly for men (Lowe et al., 2019).

Women of Underrepresented Groups

Women within underrepresented groups may experience more conflicting feelings and psychological stressors than do men in trying to adjust to both their

defined role in the underrepresented culture and a different role in the larger predominant society. Stress from acculturation, stigma toward mental illness, and lack of social support contribute to depression among immigrant women (Ganann et al., 2020). Negative stereotypic attitudes of health care providers may also contribute to reluctance to access mental health care (Kapadia et al., 2018).

Rural Cultures

Most mental health services are in urban areas because most people live near cities. Those living in rural areas have limited access to health care, which leads to fewer people being diagnosed with a mental health problem. Even though rural residents are less likely than urban residents to have mental health diagnoses or receive mental health care, the suicide rate is higher in the rural areas with firearms most commonly used (Marino et al., 2018; Stein et al., 2017). Rural areas are also diverse in both geography and culture. For example, access to mental health for those in the deep South is different from access for those with the same problems in the Northwest. Treatment approaches may be accepted in one part of the country but not in another. Suicide rates are higher in rural areas when compared to urban areas.

SPIRITUALITY, RELIGION, AND MENTAL ILLNESS

Both spirituality and religion are factors that may influence beliefs about mental illness and impact treatment and recovery.

KEYCONCEPT Spirituality develops over time and is a dynamic, conscious process. Although it is not easily defined, there is general agreement that five attributes best describe the essence of spirituality: meaning, belief, connecting, self-transcendence, and value. *Meaning* involves making sense of life and having a purpose to exist. *Belief* provides a coping mechanism and facilitates hope by having something to have faith in. *Connecting* with a higher power and relationships with family and friends serve as an important support for persons in crisis. *Self-transcendence*, the experience and appreciation of a dimension beyond oneself, facilitates spiritual growth. *Value* identifies objects that have value to the person (Stephenson et al., 2017).

Related but different than spirituality, **religiousness** is the participation in a community of people who gather around common ways of worshiping. Spirituality can be expressed through adhering to a set of religious beliefs. Religious beliefs often define an individual's relationship within a family and community. Many different religions are practiced throughout the world. Judeo-Christian thinking tends to dominate Western societies. Other religions, such as Islam, Hinduism, and Buddhism, dominate Eastern and Middle Eastern cultures (Table 3.1). Because religious beliefs often influence approaches to mental health, it is important to understand the basis of various religions that appear to be growing in the United States. Both religion and spirituality can provide support and strength in dealing with mental illnesses and emotional problems.

Table 3-1: Major World Religions and Belief Forms

Source of Power or Force (Deity)	Historical Sacred Texts or Beliefs	Key Beliefs or Ethical Life Philosophy
Buddhism		
Buddha individual responsibility and logical or intuitive thinking Buddhist subjects include	Tripitaka (scripture) Middle Path (way of life) The Four Noble Truths	Buddhism attempts to deal with problems of human existence such as suffering and death. Life is misery, unhappiness, and suffering with no ultimate reality in the world or behind it.
<ul style="list-style-type: none"> • <i>Lamaism</i> (Tibet), in which Buddhism is blended with spirit worship; • <i>Mantrayana</i> (Himalayan area, Mongolia, Japan), in which intimate relationship with a guru 	<ul style="list-style-type: none"> • Eightfold Path (guides for life) • The Texts of Taoism (include the Tao Te Ching of Lao Tzu and The Writings of Chuang Tzu) 	<ul style="list-style-type: none"> • The cause of all human suffering and misery is desire. • The “middle path” of life avoids the personal extremes of self-denial and self-indulgence. Visions can be gained through personal meditation and contemplation; good deeds and compassion also facilitate the process toward nirvana, the ultimate mode of existence. The end of suffering is the extinction of desire and emotion and ultimately the unreal self. Present behavior

- recitations of Sutras is a result of past deed.
 secret mantras are (Buddhist
 emphasized; belief commentaries)
 in sexual Sangha
 symbolism and (Buddhist
 demons; Community)
- *Ch'an* (China) *Zen* (Japan), in which self-reliance and awareness through intuitive understanding are stressed;
 - *Satori* (enlightenment) may come from "sudden insight" or through self-discipline, meditation, and instruction.

Christianity

God, a unity in tripersonality; Father, Son, and Holy Ghost.	Bible Teachings of Jesus through the apostles and the church fathers	God's love for all creatures is a basic belief. Salvation is gained by those who have faith and show humility toward God. Brotherly love is emphasized in acts of charity, kindness, and forgiveness.
--	---	---

Confucianism

No doctrine of a God or Gods or life after death. Individual responsibility and logical and intuitive	Five Classics (Confucian thought) Analects (conversations and sayings of	A philosophy or a system of ethics for living rather than a religion that teaches how people should act toward one another. People are born "good." Moral character is stressed through sincerity in personal and public behavior. Respect is shown for
--	---	--

thinking.	Confucius)	parents and figures of authority. Improvement is gained through self-responsibility, introspection, and compassion for others.
-----------	------------	--

Hinduism

Brahma (the Infinite Being and Creator that pervades all reality) Other Gods: Vishnu (preserver), Shiva (destroyer), Krishna (love)	Vedas (doctrine and commentaries)	All people are assigned to castes (permanent hereditary orders, each having different privileges in society; each was created from different parts of Brahma): <ol style="list-style-type: none"> 1. <i>Brahmans</i>: includes priests and intellectuals. 2. <i>Kshatriyas</i>: includes rulers and soldiers. 3. <i>Vaisya</i>: includes farmers, skilled workers, and merchants. 4. <i>Sudras</i>: includes those who serve the other three castes (servants, laborers, peasants). 5. <i>Untouchables</i>: the outcasts; those not included in the other castes.
--	-----------------------------------	---

Islam

Allah (the only God) Has two major sects: <ul style="list-style-type: none"> • <i>Sunni</i> (orthodox): traditional and simple practices are followed; human will is determined by outside forces. • <i>Shiite</i>: practices are rapturous and trancelike; human beings have free will. 	Koran (the words of God delivered to Mohammed by the angel Gabriel) Hadith (commentaries by Mohammed) Five Pillars of Islam (religious conduct) Islam was built on Christianity and Judaism	God is just and merciful; humans are limited and sinful. God rewards the good and punishes the sinful. Mohammed, through the Koran, guides people and teaches them truth. Peace is gained through submission to Allah. The sinless go to Paradise, and the evil go to Hell. A "good" Muslim obeys the Five Pillars of Islam.
--	--	--

Judaism

God	Hebrew Bible (Old Testament) Torah (first five books of Hebrew Bible) Talmud (commentaries on the Torah)	Jews have a special relationship with God: obeying God's law through ethical behavior and ritual obedience earns the mercy and justice of God. God is worshiped through love, not out of fear.
-----	--	--

Shintoism

Gods of nature, ancestor worship, national heroes.	Tradition and custom (the way of the Gods) Beliefs were influenced by Confucianism and Buddhism	Reverence for ancestors and a traditional Japanese way of life are emphasized. Loyalty to places and locations where one lives or works and purity and balance in physical and mental life are major motivators of personal conduct.
--	---	--

Taoism

All the forces in nature.	Tao-te-Ching ("The Way and the Power")	Quiet and happy harmony with nature is the key belief. Peace and contentment are found in the personal behaviors of optimism, passivity, humility, and internal calmness. Humility is an especially valued virtue. Conformity to the rhythm of nature and the universe leads to a simple, natural, and ideal life.
---------------------------	--	--

Tribal Beliefs

<i>Animism:</i> Souls or spirits embodied in all beings and everything in nature (trees, rivers, mountains). <i>Polytheism:</i> Many Gods, in the basic powers of nature (sun,	Passed on through ceremonies, rituals, myths, and legends Oral history, rather than written	All living things are related. Respect for powers of nature and pleasing the spirits are fundamental beliefs to meet the basic and practical needs for food, fertility, health, and interpersonal relationships and individual development. Harmonious living is comprehension and respect of natural forces.
--	---	---

moon, earth, water). literature, is
the common
medium

Summary of Other Belief Forms

- *Agnosticism*: the belief that whether there is a God and a spiritual world, or any ultimate reality is unknown and probably unknowable.
- *Atheism*: the belief that no God or Deity exists.
- *Maoism*: the faith that is centered in the leadership of the Communist Party and all the people; the major belief goal is to move away from individual personal desires and ambitions toward viewing and serving all people as a whole.
- *Scientism*: the belief that values and guidance for living come from scientific knowledge, principles, and practices; systematic study and analysis of life, rather than superstition, lead to true understanding and practice of life.

People with mental illness benefit from spiritual assessment and interventions (see [Chapter 11](#)). Perception of well-being and health in persons with severe mental illness has been positively associated with spirituality and religiousness ([Box 3.3](#)). To carry out spiritual interventions, the nurse enters a therapeutic relationship with the patient and uses the self as a therapeutic tool. Examples of spiritual interventions include meditation; guided imagery; and, when appropriate, prayer to connect with inner sources of solace and hope.

Box 3.3

The Effects of Religiosity and Spirituality on Mental Health

Peres, M. F. P., Kamei, H. H., Tobo, P. R., & Lucchetti, G. (2018). Mechanisms behind religiosity and spirituality's effect on mental health, quality of life and well-being. *Journal of Religion & Health*, 57(5), 1843–1855.

THE QUESTION: What spirituality and religiosity aspects are related to quality of life, well-being, and mental health in a general population?

METHODS: A cross-sectional sample of 967 Brazilians were asked to complete questionnaires related to religiousness, faith-peace-meaning, optimism, life satisfaction, happiness, and quality of life.

FINDINGS: From the sample, 80% completed the survey. Participants had a mean age of 34 years,

and 51% were female. All participants were married and had a university- level education. Participants identified as Catholics (43.5%), Protestants (7.4%), Spiritists (5.9%), and no religious affiliation or were atheists/agnostics (15.7%).

Meaning and peace were associated with less depressive symptoms and more physical, psychological, social, and environmental quality of life. Peace was also associated with less perceived stress. Faith was associated with more psychological and social quality of life. Meaning and peace were more strongly associated than religiousness with quality of life, mental health, and less stress. Religious participants found greater meaning and peace than nonreligious participants.

IMPLICATIONS FOR NURSING: Helping a person develops meaning, and peace supports positive mental health and quality of life.

SUMMARY OF KEY POINTS

- The term *culture* is defined as a way of life that manifests the learned beliefs, values, and accepted behaviors that are transmitted socially within a specific group. Culture also refers to age, gender, sexual orientation, disability, religion, income level, education, geographical location, or profession.
- Everyone has a cultural identity, which helps define expected behavior.
- Cultural and linguistic competence is based on a set of skills that allows individuals to increase their understanding and appreciation of cultural differences and similarities within, among, and between groups. Cultural competence is demonstrated by valuing the culture beliefs, bridging any language gap, and considering the patient's literacy level when planning and implementing care.
- Mental illnesses are stigmatized in many cultural groups. A variety of cultural and religious beliefs underlie the stigmatization.
- Access to mental health treatment is particularly limited for those living in rural areas or those who live in poverty.
- Spirituality can be a source of strength and support for both the patient with mental illness and the nurse providing the care.
- Religious beliefs are closely intertwined with beliefs about health and mental illness.

CRITICAL THINKING CHALLENGES

1. Assess your cultural competence with groups that have the following heritage: African, Asian, Hispanic, Arabic, and Native American.
2. Compare beliefs about mental illnesses within African and Asian American groups.
3. Compare the access to mental health services in your state or county in rural areas versus urban areas.
4. Discuss the differences between spirituality and religiousness. Is it possible that someone can be spiritual and not religious?
5. Identify the religious groups that are associated with the following sacred texts: *Bible*, *Koran*, *Vedas*, Texts of Taoism, and *Talmud*.

Unfolding Patient Stories: Li Na Chen

Part 1 (Chinese Family)

Li Na Chen is a 40-year-old Chinese female diagnosed with major depressive disorder who

attempted suicide by drug overdose. She is married with two children, ages 12 and 14. Why is it important for the nurse to conduct a cultural assessment of the client and her family? Describe methods the nurse can use to demonstrate cultural competence and avoid inaccurate assumptions about the Chinese culture? What questions can the nurse ask to assess cultural beliefs, practices, and influences on Li Na's mental illness and family functioning?

Movie Viewing Guides

The Big Sick (2017), a comedy, is based on a true story of Kumail Nanjiani (comedian) and Emily Gardner (writer). Kumail Nanjiani, who stars as himself, immigrated to the United States from Pakistan with his family. Kumail and Emily (Zoe Kazan) fall in love but struggle when their cultures clash. Kumail is expected to live by the traditions of his Muslim parents. Kumail's family is very close and always have dinner together; Emily lives far from her family. Kumail's mother is constantly trying to set up an arranged marriage for him. Emily develops a mysterious illness that forces her to be placed in a medically induced coma, which forces Kumail to negotiate Emily's medical crisis and her parents with his family's expectations.

VIEWING POINTS: Identify the cultural differences between Kumail's and Emily's families. Are any cultural stereotypes depicted in the film? Discuss the

role of prejudice and discrimination in the outcome of the movie.

Patient Rights and Legal Issues

Rebecca Luebbert

KEYCONCEPTS

- self-determinism

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Define self-determinism and its implications in mental health care.

2. Discuss the legal protection of the rights of people with mental illness.
3. Discuss the legal determination of competency.
4. Delineate the differences between voluntary and involuntary treatment.
5. Discuss the difference between privacy and confidentiality.
6. Discuss Health Insurance Portability and Accountability Act and mandates to inform and their implications in psychiatric–mental health care.
7. Describe the persons with mental illness in forensic settings.
8. Discuss the stigma of mental illness and criminality.
9. Describe legal outcomes for persons with mental illness in forensic settings.
10. Identify the importance of accurate, quality documentation in electronic and nonelectronic patient records.

KEY TERMS

- Accreditation
 - Advance care directives
 - Assault
 - Breach of confidentiality
 - Chemical restraint
 - Competence
 - Confidentiality
 - External advocacy system
 - Incompetent
 - Informed consent
 - Internal rights protection system
 - Involuntary commitment
 - Least restrictive environment
 - Living will
 - Medical battery
 - Negligence
 - Power of attorney
 - Privacy
 - Restraint
 - Seclusion
 - Voluntary admission
 - Voluntary commitment
-

INTRODUCTION

Because individuals with mental disorders are often vulnerable to mistreatment and abuse, their legal rights and the ethical health care practices of mental health providers are ongoing concerns for psychiatric–mental health nurses. For example, can a person be forced into a hospital if their behavior is bizarre but harmless? What human rights can be denied to a person who has a mental disorder and under what circumstances? These questions are not easily answered. This chapter summarizes some of the key patient rights and legal issues that underlie psychiatric–mental health nursing practice across the continuum of care.

SELF-DETERMINISM: A FUNDAMENTAL RIGHT AND NEED

At the foundation of many questions related to the rights of mental health patients is the issue of self-determinism and preservation of this right.

A self-determined individual is internally motivated to make choices based on personal goals, not to please others or to be rewarded. That is, a person engages in activities that are interesting, challenging, pleasing, exciting, or fun, requiring no rewards other than the positive feelings that accompany them because of inner goals, needs, drives, or preferences. Personal autonomy and avoidance of dependence on others are key values of self-determinism, which is integral to the recovery process (see [Chapter 2](#)).

In mental health care, self-determinism is the right to choose one's own health-related behaviors, which at times differ from those recommended by health professionals. A patient's right to refuse treatment, to choose an alternate treatment, and to seek a second opinion are all self-deterministic acts. In mental health care, adhering to treatment regimens may be at odds with the self-deterministic views of an individual. Patients may decline taking medication for many reasons, including denial or lack of insight of their illness, concerns about potential side effects or cost of medications, and perceived stigma associated with taking a psychotropic medication (Barloon & Hilliard, 2016). Supporting a

person's ability to choose treatment becomes complex because of related issues of competency, informed consent, voluntary and involuntary commitment, and public safety; these issues are discussed later in this chapter.

KEYCONCEPT Self-determinism is based on a person's fundamental right to autonomy. Exercising this right, patients may choose to "accept, refuse, or terminate treatment without deceit, undue influence, duress, coercion, or prejudice" (American Nurses Association, 2015, p. 2).

PROTECTION OF PATIENT RIGHTS

Because people with psychiatric problems are vulnerable to mistreatment and abuse, laws exist that guarantee them legal protection. These laws offer protection of self-determinism, protection against discrimination in employment, and protection against mistreatment in health care settings.

Self-Determination Act

The Patient Self-Determination Act was implemented on December 1, 1991, as a part of the Omnibus Budget Reconciliation Act of 1990 and requires hospitals, health maintenance organizations, skilled nursing facilities, home health agencies, and hospices receiving Medicare and Medicaid reimbursement to inform patients at the time of admission of their right to be a central part of any and all health care decisions made about them or for them. Patients have the following rights:

- Be provided with information regarding advance care documents.
- Be asked at admission or enrollment whether they have an advance care document and that this fact be recorded in the medical record.
- Be provided with information on their rights to complete advance care documents and refuse medical care (*Omnibus Budget Reconciliation Act, 1990*).

The Act also requires health care institutions receiving Medicare and Medicaid reimbursement to educate health care personnel and the local community about advance care planning.

Advance Care Directives in Mental Health

At different times during the course of an illness, people with mental disorders may be unable to make sound decisions regarding their treatment and care. Fortunately, advance care directives legally protect them from their periodic poor decision-making abilities. A competent individual can make a decision about a treatment—a decision that can be honored even if the person is no longer able to make decisions. (See later discussion for how competency is determined.)

Advance care directives are written instructions for health care when individuals are incapacitated. Living wills and appointment directives, often referred to as **power of attorney** or health proxies, are recognized under state laws and their courts. A **living will** specifies what treatment should be omitted or refused in the event that a person is unable to make those decisions. A **durable power of attorney** for health care appoints a proxy, usually a relative or trusted friend, to make health care decisions on an individual's behalf if that person is incapacitated.

An advance directive does not need to be written, reviewed, or signed by an attorney. It must be witnessed by two people and notarized and applies only if the individual is unable to make their own decisions as a result of being incapacitated or if, in the opinion of two physicians, the person is otherwise unable to make decisions for themselves.

Psychiatric advance directives (PADs) allow patients, while competent, to document their choices of treatment and care. This declaration must be made in advance and signed by the patient and two witnesses. Through the use of a PAD, individuals are empowered to direct their treatment such as choice of medication and hospitalization. Although a physician can override this declaration during times when the patient's decision-making capacity is clearly distorted because of mental illness, the patient must be informed first and the order made by the court. During periods of competency, the PAD can be revoked.

Bill of Rights for Mental Health Patients

Rights of people with mental disorders receive additional protection beyond that afforded to patients in other health care areas ([Box 4.1](#)). The *Mental Health Systems Act* [42 U.S.C. 9501 et seq.] of 1980 requires that each state review and revise, if necessary, its laws to ensure that mental health patients receive these

human rights protections and services that they require.

Americans with Disabilities Act and Job Discrimination

The *Americans with Disabilities Act* of 1990 ensures that people with disabilities, including those with mental illnesses and addictions, have legal protection against discrimination in the workplace, housing, public programs, transportation, and telecommunications. An employer is free to select the most qualified applicant available, but if the most qualified person has a mental disorder, this law mandates that reasonable accommodations need to be made for that individual. Accommodations include any adjustments to a job or work environment, such as restructuring a job, modifying work schedules, and acquiring or modifying equipment (U.S. Equal Employment Opportunity Commission, Office of the Americans with Disabilities Act, 2020).

Access to Mental Health Services

Mental health services are one of the 10 designated Essential Health Benefits requiring coverage through plans established by the Patient Protection and Affordable Care Act. Services required include behavioral health treatment, counseling, and psychotherapy. The Mental Health Parity and Addiction Equity Act requires insurance plans to offer comparable benefits and coverage for mental and substance disorders that are offered for medical and surgical coverage. Treatment fees and limitations for mental health services cannot be any more restrictive than those designated for medical care (Substance Abuse and Mental Health Services Administration [SAMHSA], 2020).

BOX 4.1

Bill of Rights for Persons Receiving Mental Health Services

- The right to appropriate treatment and related services under conditions that support the person's personal liberty and restrict such liberty only as necessary to comply with treatment needs, laws, and

judicial orders.

- The right to an individualized, written treatment or service plan (to be developed promptly after admission), treatment based on the plan, periodic review and reassessment of needs, and appropriate revisions of the plan, including a description of services that may be needed after discharge.
- The right to ongoing participation in the planning of services to be provided and in the development and periodic revision of the treatment plan, and the right to be provided with a reasonable explanation of all aspects of one's own condition and treatment.
- The right to refuse treatment, except during an emergency situation or as permitted under law in the case of a person committed by a court for treatment.
- The right not to participate in experimentation in the absence of the patient's informed, voluntary, written consent; the right to appropriate protections associated with such participation; and the right to an opportunity to revoke such consent.
- The right to freedom from restraints or seclusion, other than during an emergency situation.
- The right to a humane treatment environment that affords reasonable protection from harm and appropriate privacy.
- The right to confidentiality of records.
- The right to access, upon request, one's own mental health care records.
- The right (in residential or inpatient care) to converse with others privately and to have access to the telephone and mails unless denial of access is documented as necessary for treatment.
- The right to be informed promptly, in appropriate language and terms, of the rights described in this section.
- The right to assert grievances with respect to infringement of the Bill of Rights, including the right to have such grievances considered in a fair, timely, and impartial procedure.
- The right of access to protection, service, and a qualified advocate in order to understand, exercise, and protect one's rights.
- The right to exercise the rights described in this section without reprisal, including reprisal in the form of denial of any appropriate, available treatment.
- The right to referral as appropriate to other providers of mental health services upon discharge.

From 42 (U.S. Code § 10841)—Restatement of bill of rights. Title V of the Mental Health Systems Act [42.U.S.C. 9501 et seq].

Internal Rights Protection Systems

Mental health care systems have **internal rights protection systems** or mechanisms to combat any violation of their patients' rights. *Public Law 99–319, the Protection and Advocacy for Mentally Ill Individuals Act* of 1986, requires each state mental health provider to establish and operate a system that protects and advocates for the rights of individuals with mental illnesses and

investigates any incidents of abuse and neglect.

External Advocacy Systems

Health organizations such as the American Hospital Association, American Healthcare Association, and the American Public Health Association serve as advocates for the rights and treatment of mental health patients and are a part of an **external advocacy system**. They are financially and administratively independent from the mental health agencies. These groups advocate through negotiation and recommendations but have no legal authority. They can resort to litigation that leads to lawsuits and consent decrees (legal mandates that are monitored by the U.S. Department of Justice) or, in some instances, a denial of accreditation to the health care institution by their certifying body.

Accreditation of Mental Health Care Delivery Systems

Patient rights are also assured of protection by an agency's **accreditation**, the recognition or approval of an institution according to the accrediting body's criteria. Accrediting bodies such as The Joint Commission require patient rights standards. The Centers for Medicare and Medicaid Services (CMS) sets patient rights standards for institutions seeking Medicare and Medicaid funding. Community mental health centers are not accredited by either the Joint Commission or CMS but by another agency, the Commission on Accreditation of Rehabilitation Facilities.

TREATMENT AND PATIENT RIGHTS

In caring for patients receiving mental health services or treatment, it is important for nurses to understand several issues related to the patient's rights to determine choices about their own treatment. These issues are related to competency, informed consent, least restrictive environment, and voluntary and involuntary treatment.

Competency

One of the most important concepts underlying the legal rights of individuals is competency to consent to or to refuse treatment. Although competency is a legal determination, it is not clearly defined across the states. It is generally agreed that **competence**, or the degree to which the patient can understand and appreciate the information given during the consent process, refers to a patient's cognitive ability to process information at a specific time. A patient may be competent to make a treatment decision at one time and not be competent at another time. Similarly, competence is also decision specific, so that a patient may be competent to decide on a simple treatment with a relatively clear consequence but may not be competent to decide about a treatment with a complex set of outcomes. A competent patient can refuse any aspect of the treatment plan.

Competency is different from rationality, which is a characteristic of a patient's decision, not of the patient's ability to make a decision. An irrational decision is one that involves hurting oneself pointlessly, such as stopping recommended treatment even though symptoms return. A person who is competent may make what appears to be an irrational decision, and it cannot be overruled by health care providers; however, if a person is judged **incompetent** (i.e., unable to understand and appreciate the information given during the consent process), it is possible to force treatment on the individual. Strong arguments are, however, made against forced treatment under these circumstances. Forced treatment denigrates individuals, and according to self-determinism theory and recovery concepts, individuals are not as likely to experience treatment success if it is externally imposed.

How is it determined that a patient is competent? Mental health legal experts generally agree that four areas should be directly assessed (Appelbaum, 2007). [Table 4.1](#) outlines these assessment areas. A patient who is competent to give informed consent should be able to achieve the following:

- Communicate choices.
- Understand relevant information.
- Appreciate the situation and its consequences.
- Use a logical thought process to compare the risks and benefits of treatment options.

Informed Consent

Individuals seeking mental health care must provide **informed consent**, a legal procedure to ensure that the patient knows the benefits and costs of treatment. Merely signing a consent document does not imply an informed consent. To provide informed consent for care, the patient must be given adequate information upon which to base decisions and actively participate in the decision-making process. Informed consent is not an option but is mandated by state laws. In most states, the law mandates that a mental health provider must inform a patient in such a way that an average reasonable person would be able to make an educated decision about the interventions.

TABLE 4-1: DETERMINATION OF COMPETENCY

Assessment Area	Definition	Patient Attributes
Communicate choices	Ability to express choices	Patient should be able to clearly indicate their treatment choice.
Understand relevant information	Capacity to comprehend the meaning of the information given about treatment	Patient should be able to paraphrase understanding of treatment.
Appreciate the situation and its consequence	Capacity to grasp what the information disorder, the need for treatment, the means specifically to the patient	Patient should be able to discuss the likely outcomes, and the reason the treatment is being suggested.
Use a logical thought process to compare the risks and benefits of treatment options	Capacity to reach a logical conclusion consistent with the starting premise	Patient should be able to discuss logical reasons for the choice of treatment.

Adapted from Appelbaum, P. (2007). Assessment of patients' competence to consent to treatment. *New England Journal of Medicine*, 357(18), 1834–1840.

Informed consent is complicated in mental health treatment. A patient must be competent to give consent, but the individual's decision-making ability often is compromised by the mental illness. This dilemma might be illustrated by a situation in which a person who is informed of medication side effects refuses

treatment, not because of the potential negative impact of the medication but because they deny the illness outright. The health care provider knows that when the person begins taking the medication, the symptoms of the illness may subside, and the decision-making ability will return.

Most institutions have policies that outline the nursing responsibilities within the informed consent process. The nurse has a key role in the process of informed consent, from structuring the written informed consent document to educating the patient about a particular procedure. The nurse makes sure that consent has been obtained before any treatment is given. Informed consent is especially important in research projects involving experimental drugs or therapies.

Least Restrictive Environment

The right to refuse treatment is related to a larger concept—the right to be treated in the **least restrictive environment**, which means that an individual cannot be restricted to an institution when they can be successfully treated in the community. In 1975, the courts ruled that a person committed to psychiatric treatment had a right to be treated in the least restrictive environment (*Dixon v. Weinberger*, 1975). Medication cannot be given unnecessarily. An individual cannot be restrained or locked in a room unless all other *less restrictive* interventions are tried first.

Seclusion and Restraint

Seclusion is the involuntary confinement of a person in a room or an area where the person is physically prevented from leaving (CMS, 2015). A patient is placed in seclusion for purposes of safety or behavioral management. The seclusion room has no furniture except a mattress and a blanket. The walls are usually padded. The room is environmentally safe, with no hanging devices, electrical outlets, or windows from which the patient could jump. When a patient is placed in seclusion, they are observed at all times.

There are several types of seclusion arrangements. Some facilities place seclusion rooms next to the nurses' stations. These seclusion rooms have an observation window. Other facilities use a modified patient room and assign a

staff member to view the patient at all times. Seclusion is an extremely negative patient experience; consequently, its use is seriously questioned, and many facilities have completely abandoned its practice (Box 4.2). Patient outcomes may actually be worse if seclusion is used.

The most restrictive safety intervention is the use of **restraint**, any manual method, physical or mechanical, that immobilizes or reduces the ability of the patient to move. The nurse must choose the least restrictive type of restraint to keep a patient safe. Wrist restraints restrict arm movement. Walking restraints or ankle restraints are used if a patient cannot risk the impulse to run from a facility but is safe to go outside and to activities. Three- and four-point restraints are applied to the wrist and ankles in bed. When five-point restraints are used, all extremities are secured, and another restraint is placed across the chest. **Chemical restraint** is the use of medications for restricting patients' behavior or their freedom of movement. These chemical restraints include medications that are not a part of their standard psychiatric treatment or that are at a higher dosage of their standard medication.

Box 4.2

Evidence for Seclusion and Restraint Use

Sailas, E., & Fenton, M. (2012). Seclusion and restraint for people with serious mental illnesses. The Cochrane Database of Systematic Reviews, (2), CD001163.

THE QUESTION: How effective are seclusion, restraint, or alternative controls for people with serious mental illness?

METHODS: A meta-analysis of the effectiveness of seclusion and restraint compared with the alternatives for persons with serious mental illnesses was conducted. Randomized controlled trials were included if they focused on the use of restraint or seclusion or strategies designed to reduce the need for restraint or seclusion in the treatment of serious mental illness. The search yielded 2155 citations. Of these, 35 studies were obtained.

FINDINGS: No controlled studies exist that evaluate the value of seclusion or restraint in those with serious mental illness. There are reports of serious adverse effects for these techniques in qualitative reviews.

IMPLICATIONS FOR NURSING: Alternative ways of dealing with unwanted or harmful behaviors need to be developed. Continuing use of seclusion or restraint must, therefore, be questioned.

Restraints should be applied only after every other intervention is used and the patient continues to be a danger to self or others. Documentation must reflect a careful assessment of the patient that indicates the need for an intervention to protect the patient from harm (CMS, 2015). In addition, nurses should document all of the previously tried de-escalation interventions before the application of restraints (see [Chapter 10](#)). Restraints should be removed when the patient regains control over their behavior. The nurse should closely observe the patient and protect them from self-injury continuously while the patient is in seclusion and/or restraints.

Definite risks are associated with the use of seclusion and restraint; consequently, its use is seriously questioned (see [Box 4.2](#)). The use of seclusion and restraint can result in psychological harm and physical injury to both the patient and staff members involved in its use. Injury rates to staff in settings involving the use of seclusion and restraint are found to be higher than in other high-risk industries. Additionally, studies have shown that patients who have been secluded or restrained prolong their treatment time and are more likely to be readmitted for further treatment (SAMHSA, 2019).

In recovery-oriented practice, the nurse is particularly sensitive to recognizing the relationship between earlier trauma and retraumatizing a person by using restraint. Trauma-informed care, being aware of, and sensitive to doing no further harm to survivors of trauma, is important in recovery-oriented practice. There is general agreement that in order to use a trauma-informed approach, the patient needs to feel connected, valued, informed, and hopeful of recovery (SAMHSA, 2014); the staff recognize the connection between earlier trauma and adult mental health problems; and staff work in mindful and empowering ways with individuals and families (Muskett, 2014).

The use of both seclusion and restraints must follow the Medicare regulations contained in the Patients' Rights Condition of Participation (CMS, 2015). Agencies that do not follow the regulations may lose their Medicare and Medicaid certification and, consequently, their funding. The application of physical restraints should also follow hospital policies. Fundamental principles for the nurse to follow when considering the use of seclusion and restraints include the following:

- Seclusion or restraint must never be used out of convenience, as a punishment, or as a means of coercion.
- Seclusion or restraint must only be used as a last resort, when all other least restrictive means are shown to be ineffective.

- Seclusion or restraint must be used for the minimal amount of time necessary to ensure the safety of the patient or others.
- When mechanical restraint is necessary, only the least number of the restraint points must be used and the individual must be under continuous observation (APNA Position Statement on the Use of Seclusion and Restraint, 2018).

Voluntary and Involuntary Treatment

Accessing the mental health delivery system is similar to seeking any other type of health care. Whether in a public or private system, the treatment setting is usually for outpatient. Treatment strategies (e.g., medication, psychotherapy) are recommended and agreed on by both the provider and the individual. Arrangements for treatment and follow-up are then made. The patient leaves the outpatient setting and is responsible for following the plan.

Inpatient treatment is generally reserved for patients who are acutely ill or have a forensic commitment. If hospitalization is required, the person enters the treatment facility, participates in the treatment planning process, and follows through with the treatment. The individual maintains all civil rights and is free to leave at any time even if it is against medical advice. In most settings, this type of admission is called a **voluntary admission**. If an individual is admitted to a public facility, the state statute may refer to the process as **voluntary commitment** rather than admission; however, in both instances, full legal rights are retained.

Involuntary commitment is the mandated treatment without the person's consent but with a court order. There are also legal provisions for people to be involuntarily committed to outpatient mental health facilities through state civil laws. Because involuntary commitment is a prerogative of the state agency, each state and the District of Columbia have separate commitment statutes; however, three common elements are found in most of these statutes. There should be evidence that the individual is (1) mentally disordered, (2) dangerous to self or others, or (3) unable to provide for basic needs (i.e., *gravely disabled*).

Patients who are involuntarily committed have the right to receive treatment, but they also may have the right to refuse it. Arguments over the rights of civilly committed patients to refuse treatment first surfaced in 1975 when a federal district court judge issued a temporary restraining order prohibiting the use of psychotropic medication against the patient's will at a state hospital in Boston.

Laws about commitment and refusal of medication vary from state to state. A separate judicial process may be necessary if an individual is determined to be incompetent to refuse medication. Forcing a patient to take medication against their will without a legal provision to do so may expose the nurse to liability (Barloon & Hilliard, 2016).

Commitment procedures vary considerably among the states. Most have provisions for an emergency short-term hospitalization of 48 to 92 hours authorized by a certified mental health provider without court approval. These emergency hospitalizations are often initiated by a concerned family member or friend. At the end of this time-limited period, either the individual agrees to voluntary treatment or extended commitment procedures are begun. The judge must order the commitment, and the individual is afforded several legal rights, including notice of the proceedings, a full hearing (jury trial if requested) in which the government must prove the grounds for commitment, and the right to legal counsel at state expense.

NCLEXNOTE Which patient is most likely a candidate for involuntary commitment? A patient who refuses to take medication or one who is singing in the street in the middle of the night disturbing the neighbors?

Answer: The patient who is singing in the night disturbing the neighbors.
Rationale: Patients have a right to refuse medication in many states and provinces. Refusing medication does not pose an immediate danger to self or others. The patient who is singing in the street is more likely to be judged as a danger to self or others.

PRIVACY AND CONFIDENTIALITY

In addition to issues related to self-determinism, privacy and confidentiality are rights requiring protection for mental health patients. **Privacy** refers to the part of an individual's personal life that is not governed by society's laws and government intrusion. Protecting an individual from intrusion is a responsibility of health care providers. **Confidentiality** pertains to an ethical duty of nondisclosure. Patients often share intimate details of their lives during the course of treatment, including personal thoughts, experiences, and behaviors. Providers who receive confidential information within their nurse-patient

relationship must protect that information from being accessed by others and resist disclosing it. Confidentiality involves two people: the individual who discloses and the person with whom the information is shared. If confidentiality is broken, a person's privacy is also violated; however, a person's privacy can be violated but confidentiality maintained. For example, if a nurse observes an adult patient reading pornography alone in their room, the patient's privacy has been violated. If the patient asks the nurse not to tell anyone and the request is honored, confidentiality is maintained.

A **breach of confidentiality** occurs when a nurse divulges a patient's personal information without the patient's consent. Examples of a breach in confidentiality include discussing a patient's problem with one of their relatives without the patient's consent and sharing patient information with another professional who is not involved in the patient's care when the individual has not given permission for the information to be shared. Maintaining confidentiality is not as easy as it first appears. For example, family members are legally excluded from receiving any information about an adult member without consent even if that member is receiving care from the family. Ideally, a patient gives consent for information to be shared with the family or has psychiatric advance care directive. Ultimately, it is the nurse's duty to safeguard both personal and clinical information in the work setting as well as off duty in all venues, including social media (American Nurses Association, 2015).

Concept Mastery Alert

Privacy is the part of the person's life that is not governed by laws.

Confidentiality is the responsibility of the health care worker to limit sharing of patient information with only those mandated to know. Confidentiality affords the patient privacy.

Health Insurance Portability and Accountability Act and Protection of Health Information

The Health Insurance Portability and Accountability Act of 1996 (HIPAA)

provides legal protection in several areas of health care, including privacy and confidentiality. This act protects working Americans from losing existing health care coverage when changing jobs and increases opportunities for purchasing health care. It regulates the use and release of patient information, especially electronic transfer of health information. Effective April 2003, HIPAA regulations require patient authorization for the release of information with the exception of that required for treatment, payment, and health care administrative operations. The release of information related to psychotherapy requires patient permission. The underlying intent is to prevent the release of information to agencies not related to health care, such as employers, without the patient's consent. When information is released, the patient must agree to the exact information that is being disclosed, the purpose of disclosure, the recipient of the information, and an expiration date for the disclosure of information (U.S. Department of Health and Human Services, 2002).

The American Recovery and Reinvestment Act of 2009 includes several provisions affecting the management of health information. For the most part, this law focuses on maintaining privacy of electronic transfer and storage of health information and communication. In the clinical area, one way of maintaining privacy is by restricting access to records by staff members unless there is a specific reason such as caring for a patient.

Mandates to Inform

At certain times, health care professionals are legally obligated to breach confidentiality. When there is a judgment that the patient has harmed any person or is about to injure someone, professionals are mandated by law to report it to authorities. The legal *duty to warn* was a result of the 1976 decision of *Tarasoff v. Regents of the University of California* (1976). In this case, a 26-year-old graduate student told university psychologists about his obsession with another student, Tatiana Tarasoff, whom he subsequently killed. Tatiana Tarasoff's parents initiated a separate civil action and brought a lawsuit against the therapist, the university, and the campus police, claiming that Tatiana's death was a result of negligence on the part of the defendants.

The plaintiffs claimed that the therapists should have warned Ms. Tarasoff that the graduate student presented a danger to her and that he should have been confined to a hospital. Both claims were originally dismissed in the lower courts,

but in 1974, the California Supreme Court reversed the lower courts' decisions and said that Ms. Tarasoff should have been warned. The high court said that psychotherapists have a duty to warn the foreseeable victims of their patients' violent actions. Because of the outcry from professional mental health organizations, the court agreed to review the case, and in 1976, the original decision was revised by the ruling that psychotherapists have a duty to exercise reasonable care in protecting the foreseeable victims of their patients' violent actions. The results of this case have had far-reaching consequences and have influenced many decisions in the United States. Although many lawsuits have been based on the Tarasoff case, most have failed. Usually, if there are clear threats of violence toward others, the therapist is mandated to warn potential victims.

NCLEXNOTE What guides the intervention for a patient who tells the nurse that they want to hurt a family member: mandate to inform or HIPAA?

Answer: Mandate to inform. Rationale: Because others are at risk for injury, the Tarasoff decision will prevail.

CRIMINAL JUDICIAL PROCESSES

In mental health, the term *forensic* pertains to legal proceedings and mandated treatment of persons with a mental illness. Individuals with mental illnesses are at higher risk for arrest than the general population and are more likely to have encounters with the criminal justice system and be convicted of a crime than those without a mental illness (Gottfried & Christopher, 2017). Despite the large number of people with mental illnesses that commit crimes, the majority of the encounters with the justice system occur when individuals with mental illness are victims of crime (National Alliance on Mental Illness, 2020).

As the number of state hospitals was dramatically reduced beginning in the 1960s, the number of persons with mental illness incarcerated in jails and prisons increased. Individuals in crisis are more likely to encounter the police versus the mental health care system. Approximately 2 million individuals with mental illness are incarcerated in prisons and jails in the United States per year, including 15% of incarcerated men and 30% of incarcerated women (National Alliance on Mental Illness, 2020). High rates of substance use and substance use

disorders are found in incarcerated adults and youth, and among both men and women. The prevalence of post-traumatic stress disorder and mood and anxiety disorders are also higher in incarcerated individuals than in the general population (Gottfried & Christopher, 2017). Individuals with schizophrenia or bipolar disorder are 10 times more likely to be in a prison or jail than in a psychiatric treatment facility (Treatment Advocacy Center, 2020).

Individuals with mental illnesses are treated in a variety of forensic settings, including county jails, correctional facilities, psychiatric hospitals, and the community. The number of admissions to state psychiatric hospitals is increasing for the first time since the 1970s because of an increase of forensic patients (Torrey et al, 2014). Forensic patients often do not receive sufficient treatment for their illness while they are incarcerated, however, and are at risk for further deterioration and revictimization (Gottfried & Christopher, 2017; National Alliance on Mental Illness, 2020).

Stigma of Criminality

Incarcerated patients suffer the combined effects of the stigma of mental illness and criminality. Although stigma is an issue for all persons with a mental illness, it is magnified for those who have committed a crime. There is often reluctance on the part of mental health professionals to treat these patients, especially if murder and childhood sexual abuse are involved. Even if the worry is unfounded, clinicians express safety concerns for themselves and other patients and may refuse to care for these patients.

When nonforensic patients receive the maximum benefit from hospitalization, they are normally discharged back into the community. For forensic patients, the community often wants a more stringent discharge threshold and unrealistically expects the hospital to guarantee compliance with community rules and structure. Treatment and the criminal justice systems are often in conflict with each other.

Fitness to Stand Trial

Once a mental illness is diagnosed in a person who has committed a crime, the individual's **fitness to stand trial** is determined. Fitness means that a person is

able to consult with a lawyer with a reasonable degree of rational understanding of the facts of the alleged crime and of the legal proceedings as spelled out in the court case of *Dusky v. United States* of 1960 (Beran & Tommey, 1979, p. 12). A person is found **unfit to stand trial** if, because of mental or physical condition, they are unable to understand the nature and purpose of the proceedings or to assist in the defense (West, 2017).

In most states, when an individual with a mental illness is found unfit to stand trial, hospitalization in a forensic mental health facility follows. The goal of this hospitalization is to help the person become *fit* to stand trial, not to treat the mental illness. Sometimes, the patient's mental illness has to be treated to attain fitness. Simply stated, to be fit to stand trial, the person must be able to communicate with counsel and assist in the defense; be able to appreciate their presence in relation to time, place, and things; be able to understand that they are in a court of justice charged with a criminal offense; show an understanding of the charges and their consequences, as well as court procedures and the roles of the judge, jury, prosecutor, and defense attorney; and have sufficient memory to relate the circumstances surrounding the alleged criminal offense.

An individual cannot be *unfit* forever. If fitness cannot be attained usually within 1 year, a hearing is held, during which the facts of the alleged crime are presented to a judge who rules on the case. If the charges are dismissed, the judge could order a civil commitment. If there is sufficient evidence to convict, the individual could be sent back to the hospital for further treatment to attain fitness. The maximum length of this additional treatment is based on the severity of the charge. For those accused of sexual-related offenses (because of mental disorder), states usually have special statutes for hospitalization and discharge (e.g., registration and community notification).

Not Guilty by Reason of Insanity

Once fitness to stand trial is established, the trial or hearing can proceed. One possible outcome is **not guilty by reason of insanity (NGRI)**. The accused is judged unable to distinguish right from wrong or to be unable to control their actions at the time of the crime. The rationale underlying this ruling is one of fairness. It is unfair to hold a person responsible if that individual does not know that the action is wrong or does not have control over their behavior.

Nearly all individuals found NGRI are also subject to involuntary

commitment in a *secure* setting. The patient cannot leave hospital grounds without court approval. A person sentenced NGRI is given a date that is equal to the time or sentence to be served if they had been guilty of the crime.

Guilty but Mentally Ill

Different from NGRI, in which *not guilty* individuals are committed to the mental health system, **guilty but mentally ill (GBMI)** is a criminal conviction, and the person is sent to the correctional system. Mental illness is considered a factor in the crime but not to the extent that the individual is incapable of knowing right from wrong or controlling their actions. The sentence for the GBMI is the same type of determinate sentence any inmate receives. Before release, every effort is made to ensure that patients will receive proper follow-up care in the community and close monitoring by parole staff. Both NGRI and GBMI persons are treated for their mental disorders, but one is treated in jail and the other in a hospital. The conditions of release are different. Whereas individuals with a GBMI are subject to the correctional system's parole decisions, those with an NGRI are discharged from the hospital through the courts upon recommendations of the forensic mental health professionals.

Probation

Probation is a sentence of conditional or revocable release under the supervision of a probation officer for a specified time. For individuals with a mental illness who have committed minor offenses, probation is sometimes used instead of jail as long as care in a treatment facility can be arranged. If treatment and rehabilitation are successful, criminal charges may be dropped and a prison record avoided. Probation is also used when a criminal has served time and continued monitoring is needed after being released from the correctional facility.

Misconceptions Regarding Insanity Pleas

There are many misconceptions about the insanity plea. One is that the insanity

defense provides a loophole through which criminals can escape punishment for illegal acts. In reality, the insanity defense is extremely difficult to use even in the cases of severely ill individuals. As a result, despite popular belief, the insanity defense is used in fewer than 1% of criminal cases ([Box 4.3](#)).

Countless newspaper articles, talk shows, and news commentaries concerning the insanity defense have bombarded the public. Some of the cases have been highly publicized. One such case was that of John Hinckley, who attempted to assassinate President Ronald Reagan in 1981 and who was found NGRI. On psychiatric examination, Hinckley was found to be living in a “fantasy world with magical and grandiose expectations of impressing and winning over” his love, actress Jodie Foster (Goldstein, 1995, p. 309). Hinckley attempted to commit a historic deed that would make him famous and unite him with the love object of his delusions. His acquittal stimulated public cries for reform of the insanity defense. Within 2.5 years of John Hinckley’s acquittal, 34 states changed their insanity defense statutes to limit its use or to prevent the premature release of dangerous people.

BOX 4.3

The Case of Andrea Yates

In March 2002, Andrea Yates, age 37 years, was convicted of murder for drowning her five children. She was sentenced to life in prison despite past treatment for postpartum depression and psychosis, four hospitalizations, and two suicide attempts. Andrea Yates was found guilty because in her testimony to the police, she stated that she knew the criminal justice system would punish her for her actions, implying that she knew the acts were wrong in the eyes of the law. Texas law does not recognize that for someone as ill as Andrea Yates, mental illnesses can create more powerful hierarchies of right and wrong than societal law. In July 2006, Andrea was granted a retrial because the previous verdict was overturned on appeal because of erroneous testimony. At the second trial, Andrea was found not guilty by reason of insanity. She was committed to a state mental hospital with periodic hearings before a judge to determine whether she should be released (Biography.com, 2020).

Gun Laws and Mental Illness

The Brady Handgun Violence Prevention Act of 1993, commonly referred to as the Brady Act or Brady Bill, was originally proposed in response to Hinckley’s assassination attempt on President Reagan. The Brady Act requires a background check on individuals seeking ownership of a firearm. Under this

Act, individuals considered mentally incompetent, having severe mental illness, or those having been committed to a mental institution are prohibited from gun ownership. There is much controversy surrounding gun control for persons with mental illness. While the laws are intended to restrict firearms in those determined to be of significant danger to others, the reality is that only a very small percentage of all violent crimes are perpetrated by individuals diagnosed with mental illness. Therefore, insisting that gun violence is strictly a mental health problem unfairly stigmatizes those with mental illness (Philpott-Jones, 2018).

ACCOUNTABILITY FOR NURSES AND OTHER MENTAL HEALTH CARE PROFESSIONALS

Nurses and other health care professionals are accountable for the care they provide in mental health as well as any other practice area.

Legal Liability in Psychiatric Nursing Practice

Malpractice is based on a set of torts (a civil wrong not based on contract committed by one person that causes injury to another). An **assault** is the threat of unlawful force to inflict bodily injury upon another. An assault must be imminent and cause reasonable apprehension in the individual. Battery is the intentional and unpermitted contact with another. **Medical battery**, intentional and unauthorized harmful or offensive contact, occurs when a patient is treated without informed consent. For example, a clinician who fails to obtain consent before performing a procedure is subject to being accused of medical battery. Also, failure to respect a patient's advance directives is considered medical battery. False imprisonment is the detention or imprisonment contrary to provision of the law. Facilities that do not discharge voluntarily committed patients upon request can be subject to this type of litigation.

Negligence is a breach of duty of reasonable care for a patient for whom a nurse is responsible that results in personal injuries. A clinician who does get consent but does not disclose the nature of the procedure and the risks involved is subject to a negligence claim. Five elements are required to prove negligence:

duty (accepting assignment to care for patient), breach of duty (failure to practice according to acceptable standards of care), cause in fact (the injury would not have happened if the standards had been followed), cause in proximity (harm actually occurred within the scope of foreseeable consequence), and damages (physical or emotional injury caused by breach of standard of care). Simple mistakes are not negligent acts.

Lawsuits in Psychiatric Mental Health Care

Few lawsuits are filed against mental health clinicians and facilities compared with other health care areas. If psychiatric nurses are included in lawsuits, they are usually included in the lawsuit filed against agency. Common areas of litigation surround the nursing care of patients who are suicidal or violent. Maintaining and documenting an appropriate standard of care can protect nurses from complicated legal proceedings. The following can help prevent negative outcomes of malpractice litigations:

- Evaluate risks, especially when privileges broaden or care is transferred.
- Document decisional processes and reasons for choices among alternatives.
- Involve family in important decisions.
- Make decisions within team model and document this shared responsibility.
- Adhere to agency's policy and procedures.
- Seek consultation and record input.

Nursing Documentation

Careful documentation is important both to help ensure protection of patient rights and for nurse accountability. Documentation can be handwritten or electronic. It is very common in psychiatric facilities that all disciplines record one progress note. Nursing documentation is based on nursing standards (see [Chapter 6](#)) and the policies of the particular facility. Many documentation styles are problem focused. That is, documentation is structured to address specific problems that are identified on the nursing care plan or interdisciplinary treatment plan. No matter the setting or structure of the documentation, nurses are responsible for documenting the following:

- Observations of the patient's subjective and objective physical, psychological, and social responses to mental disorders and emotional problems
- Interventions implemented and the patient's response
- Observations of therapeutic and side effects of medications
- Evaluation of outcomes of interventions

Particular attention should be paid to the reason the patient is admitted for care. If the person's initial problem was suicide or homicidal ideation, the patient should routinely be assessed for suicidal and homicidal thoughts even if the treatment plan does not specifically identify suicide and homicide as potential problems. Careful documentation is always needed for patients who are suicidal, homicidal, aggressive, or restrained in any way. Medications prescribed as needed (*pro re nata*) also require a separate entry, including reason for administration, dosage, route, and response to the medication.

A patient record is the primary documentation of a patient's problems, verifies the behavior of the patient at the point of care, and describes the care provided. The patient record is considered a legal document. Courts consider acts not recorded as acts not done. Patients also have legal access to their records. For handwritten documentation, the entries should always be written in pen with no erasures. If an entry is corrected, it should be initialed by the person making the correction. All entries should be clear, well written, and void of jargon. Judgmental statements, such as *patient is manipulating staff*, have no place in patients' records. Only meaningful, accurate, objective descriptions of behavior should be used. General, stereotypic statements, such as *had a good night* or *no complaints*, are meaningless and should be avoided.

With the universal use of electronic records, meaningful documentation is sometimes more difficult. Many institutions require health care workers to enter observations, assessment data, and interventions into a template that requires a *click* in a box on the monitor screen. Additional narrative entries are usually required to provide quality, individualized care. Nurses should adhere to the same standards of practice and documentation when entering electronic data as when entering data in a non-electronic record.

SUMMARY OF KEY POINTS

- The right of self-determination entitles all patients to refuse treatment, to obtain other opinions, and to choose other forms of treatment. It is one of the basic patients' rights established by Title II, Public Law 99–139, outlining the Universal Bill of Rights for Mental Health Patients.
- Laws and systems are established to protect the rights of people with mental health issues. Some of these include the Self-Determination Act, advance directives, a patient Bill of Rights, the Americans with Disabilities Act, internal rights protection systems, external advocacy systems, and accreditation of mental health care delivery systems.
- The internal rights protection system and the external advocates combat violations of human rights.
- Informed consent is another protective right that helps patients decide what can be done to their bodies and minds. It must be obtained from a competent individual before any treatment is begun to ensure that the information is not only received but also understood.
- A competent person can refuse any treatment. Incompetence is determined by the court when the patient cannot understand the information.
- The right to the least restrictive environment entitles patients to be treated in the least restrictive setting and by the least restrictive interventions and protects patients from unnecessary confinement and medication.
- Seclusion or restraint should be used as a last resort and only when

there is risk of harm to the patient or someone else. Patients secluded or restrained should be under continuous observation by staff.

- Involuntary commitment procedures are specified at the state level. Patients who are involuntarily committed have the right to refuse treatment and medication.
- Patient privacy is protected through HIPAA regulations related to the transfer and storage of information. A breach in confidentiality is legally mandated when there is a threat of violence toward others.
- Nursing documentation is guided by practice standards and policies of the agency. Nurses are responsible for individualized documentation in both electronic and nonelectronic health records.

CRITICAL THINKING CHALLENGES

1. Consider the relationship of self-determinism to competence by differentiating patients who are competent to give consent and those who are incompetent. Discuss the steps in determining whether a patient is competent to provide informed consent for a treatment.
2. Define competency to consent to or refuse treatment and relate the definition to the Self-Determination Act.
3. A patient is involuntarily admitted to a psychiatric unit and refuses all medication. After being unable to persuade the patient to take prescribed medication, the nurse documents the patient's refusal and notifies the prescriber. Should the nurse attempt to give the medication without patient consent? Support your answer.
4. A person who is homeless with a mental illness refuses any treatment. Although he is clearly psychotic and would benefit from treatment, he is not a danger to himself or others and seems to be able to provide for his basic needs. His family is desperate for him to be treated. What are the ethical issues underlying this situation?
5. Discuss the purposes of living wills and health proxies. Discuss their use in psychiatric–mental health care.
6. Identify the legal and ethical issues underlying the Tarasoff case and mandates to inform.
7. Compare the authority and responsibilities of the internal rights protection system with those of the

external advocacy system.

Movie Viewing Guides

Lady in the Van: (2015). This movie is based on a true story about Miss Mary Shepherd (Maggie Smith), an eccentric, homeless woman, who temporarily parked her old van in the driveway of Allen Bennett's (Alex Jennings) upper-middle-class home in Camden, England. She stayed for 15 years. The story depicts the strained relationship as he tried to humanely move her to more suitable housing. As the story develops, Bennett learns that Miss Shepherd is really Margaret Fairchild (died in 1989), a former gifted pupil of the pianist Alfred Cortot. She had played Chopin in a promenade concert, had tried to become a nun, was committed to an institution by her brother, had escaped, had had an accident when her van was hit by a motorcyclist for which she believed herself to blame, and thereafter lived in fear of arrest.

VIEWING POINTS: How does the relationship between Mary Shepard and Allen Bennett change during the 15-year period. Are Miss Shepard's rights being violated? Does she have the right to remain parked in Mr. Bennett's driveway. What legal measures were used in the movie?

Mental Health Care in the Community

Mary Ann Boyd

KEYCONCEPTS

- case management
- continuum of care

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Define and explain continuum of care for mental health services.
2. Explain how the concept of the least restrictive environment influences the choice of treatment settings.
3. Identify various mental health treatment settings and associated programs along the continuum of care.
4. Discuss the role of the psychiatric nurse at different points along the continuum of care.
5. Describe the integration of psychiatric and medical care in community settings.

KEY TERMS

- 23-hour observation
 - Assertive community treatment
 - Board-and-care homes
 - Case management
 - Coordination of care
 - Crisis intervention
 - Crisis intervention teams
 - Digital applications
 - In-home mental health care
 - Integrated care
 - Intensive case management
 - Intensive outpatient program
 - Intensive residential services
 - Medical home
 - Outpatient detoxification
 - Partial hospitalization
 - Peer support services
 - Psychiatric rehabilitation programs
 - Recovery centers
 - Reintegration
 - Relapse
 - Residential services
 - Telehealth
 - Therapeutic foster care
 - Transfer
 - Transitional care
-

INTRODUCTION

The evolution of a behavioral health care system is affected by scientific advances and social factors. Recovery from mental illness is a goal at all stages of treatment. The long-term nature of mental illnesses requires varying levels of care at different stages of the disorders as well as family and community support. Treatment costs are shared among public and private sectors. A demand exists for a comprehensive, holistic approach to care that encompasses all levels of need. Consumers, families, providers, advocacy groups, and third-party payers of mental health care no longer accept long-term institutionalization, once the hallmark of psychiatric care. Instead, they advocate for short-term treatment in an environment that promotes dignity and well-being while meeting the patient's biologic, psychological, and social needs.

Reimbursement issues influence health care delivery. In the United States, health maintenance organizations, preferred provider organizations, Medicaid, and Medicare have set limits on the types and lengths of treatment for which they provide reimbursement coverage, which in turn influences the kind of care the patient receives. In other countries, other regulatory bodies influence access and treatment options. Fragmentation of services is a constant threat. Today, psychiatric–mental health nurses face the challenge of providing mental health care within a complex system that is affected by financial constraints and narrowed treatment requirements.

DEFINING THE CONTINUUM OF CARE

A continuum of care that supports recovery can be viewed from various perspectives and ranges from intensive treatment (hospitalization) to supportive interventions (outpatient therapy). An individual's needs for ongoing clinical treatment and care are matched with the intensity of professional health services.

In a continuum, continuity of care is provided over an extended time. The appropriate medical, nursing, psychological, or social services may be delivered within one organization or across multiple organizations. The continuum facilitates the stability, continuity, and comprehensiveness of service to an individual and maximizes the coordination of care and services.

KEYCONCEPT A **continuum of care** consists of an integrated system of settings, services, health care clinicians, and care levels, spanning illness-to-wellness states.

Least Restrictive Environment

The primary goal of the continuum of care is to provide treatment that supports recovery in the **least restrictive environment** (see [Chapter 4](#)). In 1999, the U.S. Supreme Court reinforced the principle of least restrictive environment with the Olmstead decision, which states that it is a violation of the Americans with Disabilities Act to institutionalize people with severe mental illnesses when services in the community are equally effective (*Olmstead v. L.C.*, 1999). Therefore, treatment is usually delivered in the community (as opposed to a hospital or institution) and, ideally, in an outpatient setting.

Coordination of Care

Coordination of care is the integration of appropriate services so that individualized care is provided. Appropriate services are those that are tailored to address a client's strengths and weaknesses, cultural context, service preferences, and recovery goals, including referral to community resources and liaisons with others (e.g., physician, health care organizations, and community services). Several agencies could be involved, but when care is coordinated, a person's needs are met without duplication of services. Coordination of care requires collaborative and cooperative relationships among many services, including primary care, public health, mental health, social services, housing, education, and criminal justice, to name a few.

In some instances, a whole array of integrated services is needed. For example, children can benefit from treatment and specialized support at home and school. These wraparound services represent a unique set of community services and natural supports individualized for the child or adult and family to achieve a positive set of outcomes.

Case Management

Coordinated care is often accomplished through a **case management** service model in which a case manager locates services, links the patient with these services, and then monitors the patient's receipt of these services. This type of case management is referred to as the *broker* model. Case management can be provided by an individual or a team; it may include both face-to-face and telephone contact with the patient as well as contact with other service providers. **Intensive case management** is targeted for adults with serious mental illnesses and children with serious emotional disturbances. Managers of such cases have fewer caseloads and higher levels of professional training than do traditional case managers.

KEYCONCEPT Case management is a professional and collaborative process that assesses, plans, implements, coordinates, monitors, and evaluates the options and services required to meet an individual's health needs. It uses communication and available resources to promote health, quality, and cost-effective outcomes in support of the 'Triple Aim,' of improving the experience of care, improving the health of populations, and reducing per capita costs of healthcare (Commission for Case Manager Certification [CCMC], 2015, p. 4).

Case management services are built on a strong working alliance between the patient and the case manager. Quality is assessed by measuring patient outcomes that result from the services, such as symptom reduction, improved functioning and community integration, and patient satisfaction with the services provided. In addition, case managers can optimize a patient's use of resources by developing a treatment plan that closely matches the individual needs of the patient and by matching the most appropriate treatment to the patient's phase of illness.

The Nurse as Case Manager

Case managers work in a variety of settings, including insurance companies, hospitals, workmen compensation, and independent organizations (Arnold, 2019). Psychiatric nurse case managers serve in various pivotal functions across the continuum of care. These functions can involve both direct care and coordination of the care delivered by others. The repertoire of required skills includes collaboration with members of a multidisciplinary team, teaching, management, leadership, group, and research skills. The nurse case manager must have firm knowledge of psychiatric nursing and be able to function

independently. This role is probably the most diverse role within the psychiatric continuum.

Virtual Health Care

Telehealth, the delivery of health-related services and information via digital communication technologies, is rapidly appearing as a primary strategy in the delivery of health care, particularly mental health throughout the continuum of care. The coronavirus disease (COVID-19) pandemic drove dramatic acceleration in the use and acceptance of digital health care as a credible option to in-person visits. Now, telehealth is preferred by many clinicians and patients in certain situations (Peek et al., 2020).

Telehealth had its beginning in the early 1900s, and as technology advanced, the impact of digital communication has assumed increasing importance (see [Table 5.1](#)). The technology was initially used as a method of storing and forwarding medical information, but its use quickly expanded to remote medical monitoring. Today, it is widely used for real-time interactive services. **Digital applications** or apps are used for all three—storing and forwarding, remote medical monitoring, and interactive services (Cassatly & Cassatly, 2017).

In mental health care, telehealth was initially viewed as a way of providing access to mental health services in rural communities because of clinician shortages, lack of public transportation, and poverty. Telehealth contact with patients after discharge from the hospital allowed nurses to assess psychiatric symptoms, check on medication adherence, discuss approaches to solving problems associated with community living, and provide emotional support. As technology advanced, more telehealth applications became available to those in rural areas.

TABLE 5.1 HISTORY OF TELEHEALTH IN U.S. HEALTH CARE

Date	Events
Early 1900s	Patient interview over telephone.
1950s	Psychiatrist–patient interaction over closed-circuit television.

- 1960s U.S. space program introduced remote medical monitoring.
 - 1990s Internet is introduced. Health professionals began sharing information electronically.
 - 1996 Institute of Medicine report—Telemedicine: A Guide to Assessing Telecommunication for Healthcare.
 - 2010 Affordable Care Act resulted in improvement in broadband support, medical networks, electronic health records.
 - 2020 Coronavirus pandemic caused a need for remote health care delivery leading to reduction in barriers and widespread use of telehealth.
-

Even though the technology supported virtual interaction, there were several barriers that prevented utilization of the service. Internet connectivity was not always available in rural areas. Clinicians were often reluctant to use technology for fear of missing indications of suicide or other safety issues. Third-party insurers were unwilling to pay for telehealth visits. An in-person visit was required before controlled substances could be prescribed, and Health Insurance Portability and Accountability Act and Privacy Standards required strict secure two-way communication preventing the use of Zoom, Skype, or FaceTime.

These barriers were relaxed or removed during the COVID-19 pandemic. Medicare began paying for office, hospital, and other visits furnished via telehealth across the country in 2020. Health Insurance Portability and Accountability Act and Privacy Standards were relaxed; visits were no longer limited to rural settings. Prescribers were able to issue prescriptions for controlled substances to patients using telemedicine without a prior in-person patient medical evaluation.

Telehealth interventions for the treatment, prevention, diagnosis, and management of depression, serious mental illness, and substance use are now used in most urban and rural settings (Box 5.1). Videoconferencing, e-mail, mobile apps, and texting are being used (Naslund et al., 2017).

BOX 5.1

Use of a Mobile App to Improve Distress

Stallman, H. M. (2019). Efficacy of the My Coping Plan mobile application in reducing distress: A randomised controlled trial. *Clinical Psychologist*, 23(3), 206–212.

THE QUESTION: Is the strengths-focused My Coping Plan app effective in improving mental

health and coping?

METHODS: Fifty-six university students with self-reported elevated levels of distress (K10 total ≥ 16) were randomly assigned to the intervention (My Coping Plan) or waitlist control condition.

RESULTS: At 1-month follow-up, participants in the intervention condition reported significantly lower psychological distress ($d = 0.31$), improved well-being ($d = -0.42$), and improved healthy coping strategies ($d = 0.39$) compared with those in the control condition. There was no significant difference between groups in reported unhealthy coping strategies. The majority of participants downloaded the app and made a coping plan. Just over half used their plan when they were distressed.

IMPLICATIONS FOR NURSING: Mobile apps have potential to improve mental health and well-being in the short term, likely through increased self-efficacy.

MENTAL HEALTH SERVICES IN A CONTINUUM OF CARE

Crisis Care

An organized approach is required to treat individuals in crisis, including a mechanism for rapid access to care (within 24 hours), a referral for hospitalization, or access to outpatient services.

Crisis Intervention

Crisis intervention—a specialized short-term, goal-directed therapy for those in acute distress—is brief, usually lasting fewer than 6 hours (see [Chapter 21](#)). This type of short-term care focuses on stabilization, symptom reduction, and prevention of relapse requiring inpatient services.

Crisis intervention units can be found in the emergency departments of general and psychiatric hospitals and in crisis centers within community mental health centers. Patients in crisis demonstrate severe symptoms of acute mental illness, including labile mood swings, suicidal ideation, or self-injurious behaviors. Therefore, this treatment option commands a high degree of nursing expertise. Patients in crisis usually require medications such as anxiolytics or benzodiazepines for symptom management. Key nursing roles include

assessment of short-term therapeutic interventions and medication administration. Nurses also facilitate referrals for admission to the hospital or for outpatient services.

Crisis intervention teams (CTI)—interdisciplinary mental health specialists and first responders—provide protection to individuals with mental illness symptoms who are a threat to self or others. Law enforcement personnel, such as police officers, are often the first responders when crises occur in the community. Police officers need to accurately assess and intervene in crisis situations and determine whether the people involved in the crisis are experiencing behavioral problems due to symptoms of mental illness. CIT have been developed to train police officers to recognize and intervene in crisis situations in the community and determine whether emergency psychiatric services are needed. Crisis intervention by CIT-trained police officers can avoid inappropriate involvement of the patient in the criminal justice system and ensure that patients with behavioral problems due to mental illnesses receive appropriate psychiatric treatment (Crisanti et al., 2019).

23-Hour Observation

The use of **23-hour observation** is a short-term treatment that serves the patient in immediate but short-term crisis. This type of care admits individuals to an inpatient setting for as long as 23 hours, during which time services are provided at a less-than-acute care level. The clinical problem usually is a transient disruption of baseline function, which will resolve quickly. Usually, the individual is experiencing suicidal or homicidal ideation, which presents a threat to themselves or others. The nurse's role in this treatment modality is assessment and monitoring. Medications also are usually administered. This treatment is used for acute trauma, such as rape and alcohol and narcotic detoxification, and for individuals with personality disorders who present with self-injurious behaviors.

Crisis Stabilization

When the immediate crisis does not resolve quickly, crisis stabilization is the

next step. This type of care usually lasts fewer than 7 days and has a symptom-based indication for hospital admission. The primary purpose of stabilization is control of precipitating symptoms through medications, behavioral interventions, and coordination with other agencies for appropriate aftercare. The major focus of nursing care in a short-term inpatient setting is symptom management. Ongoing assessment; short-term, focused interventions; and medication administration and monitoring of efficacy and side effects are major components of nursing care during stabilization. Nurses may also provide focused group psychotherapy designed to develop and strengthen the personal management strategies of patients. When treating aggressive or violent patients, the nurse implements the appropriate use of seclusion and restraints according to facility policy.

Acute Inpatient Care

Acute inpatient hospitalization is the most intensive treatment and occurs in the most restrictive setting in the continuum. Inpatient treatment is reserved for acutely ill patients who, because of a mental illness, meet one or more of three criteria: high risk for harming themselves, high risk for harming others, or unable to care for their basic needs. Delivery of inpatient care can occur in a psychiatric hospital, psychiatric unit within a general hospital, or public-operated facility. Nursing care is critical in the acute care setting and is provided around the clock.

Admission to inpatient environments can be voluntary or involuntary (see [Chapter 4](#)). The average length of stay for an involuntary admission ranges between 24 hours and several days, depending on the state or province laws; the length of stay for a voluntary admission depends on the acuity of symptoms and the patient's ability to pay the costs of treatment. It is unconstitutional in the United States to confine a nondangerous person with a mental illness with an involuntary hospitalization when the patient can survive independently with the help of willing and responsible family or friends. Nevertheless, the interdisciplinary treatment team determines that the patient is no longer at risk to themselves or others before discharge can occur.

Both the number of available beds in psychiatric hospitals in the United States and length of inpatient stay have continually decreased since the 1980s, a trend attributed to managed care and expansion of multidisciplinary, intensive

community-based services, such as **assertive community treatment (ACT)**. Additional contributors to decreased length of stay include strict admission criteria and regulations that determine the need for continued hospitalization. Currently, admission to a hospital is determined based on medical necessity, such as dangerousness or the need for crisis stabilization. Discharge is a complex process that varies from setting to setting often depending on the resources of individual, hospital, and community systems (Xiao et al., 2019).

Partial Hospitalization

Partial hospitalization programs (PHPs), also referred to as day treatment programs, were developed to complement inpatient mental health care and outpatient services and provide treatment to patients with acute psychiatric symptoms who are experiencing a decline in social or occupational functioning, who cannot function autonomously on a daily basis, or who do not pose imminent danger to themselves or others. It is a time-limited, ambulatory, active treatment program that offers therapeutically intensive, coordinated, and structured clinical services within a stable milieu. The aim of PHPs is patient stabilization without hospitalization or reduced length of inpatient care. An alternative to inpatient treatment, PHP usually provides the resources to support therapeutic activities both for full-day and half-day programs. This level of care does not include overnight hospital care; however, the patient can be admitted for inpatient care within 24 hours.

In **partial hospitalization**, the interdisciplinary treatment team partners with the patient and devises and executes a comprehensive plan of care encompassing behavioral therapy, social skills training, basic living skills training, education regarding illness and symptom identification and relapse prevention, community survival skills training, relaxation training, nutrition and exercise counseling, and other forms of expressive therapy. Group-based services such as wellness education and counseling for comorbid serious mental illnesses and substance abuse are also provided (Taube-Schiff et al., 2019). Compared with other outpatient programs, PHPs offer more intensive nursing care.

Residential Services

Residential services provide a place for people to reside during a 24-hour period or any portion of the day on an ongoing basis. A residential facility can be publicly or privately owned. **Intensive residential services** are intensively staffed for patient treatment. These services may include medical, nursing, psychosocial, vocational, recreational, or other support services. Combining residential care and mental health services, this treatment form offers rehabilitation and therapy to people with serious and persistent mental illnesses, including chronic schizophrenia, bipolar disorder, and unrelenting depression. These services may provide short-term treatment for stays from 24 hours to 3 or 6 months or long-term treatment for several months to years.

As a result of deinstitutionalization, many patients who were unable to live independently were discharged from state hospitals to intermediate- or skilled-care nursing facilities. The use of nursing homes for residential care is controversial because many of these facilities lack mental health services. Residential care in nursing homes varies from state to state. If a facility serves a primarily geriatric population, placement of younger persons there can be problematic. If a facility with more than 16 beds is engaged primarily in providing diagnosis, treatment, or care of persons with mental disorders (including medical attention, nursing care, and related services), it is designated by the federal government as an institution for mental disease (IMD). A Medicare-certified facility having more than 16 beds and at least 50% of residents with a mental disorder is also considered an IMD. An IMD may not qualify for matching federal Medicaid dollars, which means that the state has principal responsibility for funding inpatient psychiatric services (Congressional Research Service, July 30, 2019).

Nursing plays an important role in the care of people who have severe and persistent mental illnesses and who require partial hospitalization or long-term stays at residential treatment facilities. Nurses provide recovery-oriented psychiatric nursing care with a focus on psychoeducation, basic social skills training, aggression management, activities of daily living training, and group living. Education on symptom management, understanding mental illnesses, and medication is essential for recovery. The *Psychiatric–Mental Health Nursing: Scope and Standards of Practice* guides the nurse in delivering patient care (American Nurses Association, American Psychiatric Nurses Association, & International Society of Psychiatric-Mental Health Nurses, 2014) (see [Chapter 11](#)).

Respite Residential Care

Sometimes, the family of a person with mental illness who lives at home may be unable to provide care continuously. In such cases, respite residential care can provide short-term necessary housing for the patient and periodic relief for the caregivers.

Transitional Care

Health service systems have established a goal of reducing readmission following discharge from the hospital. Risk for 30-day readmission following discharge is high among people diagnosed with mental illnesses (Lewis et al., 2019). People with serious mental illnesses need support and access to community resources when they are discharged from inpatient hospitalization but are often unable to access resources due to cognitive impairments, poor problem-solving skills, social isolation, unstable housing, and poverty. Access to these resources is critically important to promote medication adherence and attendance at the first follow-up appointment following discharge from the hospital.

Transitional care interventions have been used in the community to ensure that people with mental illnesses stay engaged in treatment between discharge from the hospital and the first follow-up appointment. Some programs provide intensive interventions immediately after discharge with reducing the intensity when the person returns for a follow-up appointment; some use peer support specialists over a long length of time (Tyler et al., 2019).

In-Home Mental Health Care

If at all possible, people with mental illnesses live at home, not in a residential treatment setting. The goals are choices, not placement; physical and social integration, not segregated and congregate grouping by disability; and individualized flexible services and support, not standardized levels of service. When a person can live at home but outpatient care does not meet the treatment needs, **in-home mental health care** may be provided. Home care emphasizes

the personal autonomy of the patient and the need for a trusting, collaborative relationship between the nurse and the patient (Roldán-Merino et al., 2013). In this setting, direct patient care and case management skills are used to decrease hospital stays and increase the functionality of the patient within the home. Individuals who most benefit from in-home mental health care include patients with chronic, persistent mental illness or patients with mental illness and comorbid medical conditions that require ongoing monitoring.

In-home mental health care services rely on the skills of the mental health nurse in providing ongoing assessment and implementing a comprehensive, individualized treatment plan of care. Components of the care plan and the ongoing assessment include data on mental health status, the environment, medication compliance, family dynamics and home safety, supportive psychotherapy, psychoeducation, coordination of services delivered by other home care staff, and communication of clinical issues to the patient's psychiatrist. In addition, the plan should address care related to collecting laboratory specimens (blood tests) and crisis intervention to reduce rehospitalization.

Outpatient Care

Outpatient care is a level of care that occurs outside of a hospital or institution. Outpatient services usually are less intensive and are provided to patients who do not require inpatient, residential, or home care environments. Many patients enroll in outpatient services immediately upon discharge from an inpatient setting. Outpatient treatment can include ongoing medication management, skills training, supportive group therapy, substance abuse counseling, social support services, and case management. People with severe mental illnesses have high rates of comorbid medical illnesses, and many outpatient mental health clinics have developed integrated mental health–primary care treatment models to address the physical health needs of those with mental illnesses. These varying services promote community **reintegration** (return and acceptance of a person as a fully participating member of a community), symptom management, and healthy lifestyle (Murphy et al., 2019).

Intensive Outpatient Programs

The primary focus of **intensive outpatient programs** is on stabilization and relapse prevention for highly vulnerable individuals who function autonomously on a daily basis. People who meet these criteria have returned to their previous lifestyles (e.g., interacting with family, resuming work, and returning to school). Attendance in this type of program benefits individuals who still require frequent monitoring and support within a therapeutic milieu that enables them to remain connected to the community. The duration of treatment and level of services rendered are based on the patient's immediate needs. The treatment duration usually is time limited, with sessions offered 3 to 4 hours per day and 2 to 3 days per week. The treatment activities of the intensive outpatient program are similar to those offered in PHPs; whereas PHPs emphasize social skills training, intensive outpatient programs teach patients about stress management, illness, medication, and relapse prevention.

Other Services Integrated into a Continuum of Care

Within the continuum of care, other outpatient services may be received separately or simultaneously within various settings. They involve discrete services and patient variables.

Peer Support Services

Peer support services are provided by mental health consumers who have experienced symptom remission and are actively involved in their own recovery from mental illness. Peer support specialists typically work in outpatient settings, such as community mental health centers, therapeutic rehabilitation centers, and **recovery centers**. The peer support specialist works with other mental health consumers who are in the process of moving toward recovery goals. The relationship between peer specialists and mental health consumers offers an opportunity for offering mutual support for coping with mental illness and reciprocal sharing of personal experiences in the process of recovery. Peer support specialists assist consumers with self-determination and personal

responsibility for recovery. They can also teach mental health consumers effective self-management skills and self-advocacy and encourage participation in wellness and recovery activities (Lapidos et al., 2018).

Outpatient Detoxification

There is an increasing shift toward providing alcohol and drug detoxification in an outpatient setting. The decision to use outpatient detoxification depends on symptom severity and types of drugs the patient uses. Patients with alcohol dependence who show signs of tolerance and withdrawal can undergo detoxification in an outpatient setting. However, patients who undergo ambulatory detoxification must have reliable family members who are available to provide monitoring. Outpatient detoxification is not suitable for situations involving severe or complicated withdrawal, especially with delirium. In addition, patients who are pregnant or have a history of a seizure disorder are hospitalized for detoxification.

Outpatient detoxification is a specialized form of partial hospitalization for patients requiring medical supervision. During the initial withdrawal phase, use of a 23-hour bed may be a treatment option, depending on the stage of withdrawal and the type of addictive substance used. Or the patient may be required to attend a detoxification program 4 to 5 days per week until symptoms resolve. The length of participation depends on the severity of addiction.

Outpatient detoxification includes a 12-step recovery model, such as Alcoholics Anonymous (AA) and Narcotics Anonymous (NA), which provides outpatient involvement with professionals experienced in addiction counseling. It encourages abstinence and provides training in stress management and relapse prevention. Al-Anon and Alateen rely on 12-step support for families, who are usually included in the treatment program.

In-Home Detoxification

Detoxification from alcohol may be done in the home. For home detoxification to be safe and effective, symptoms of withdrawal must be mild, and a family member must be present at all times. The nurse is required to visit the patient

daily for medication monitoring during the patient's first week of sobriety. Daily visits are necessary until the patient is in a medically stable condition. Referrals may come from primary care physicians, court mandates, or employee assistance programs.

Assertive Community Treatment

The ACT model is a multidisciplinary clinical team approach providing 24-hour, intensive community-based services. ACT typically includes low staff-to-patient ratios, but this may not be possible in rural areas with shortages of qualified mental health professionals and few services (Spivak et al., 2019). The ACT model helps individuals with serious mental illness live in the community by providing a comprehensive range of treatments, rehabilitation, and supportive services to help patients meet the requirements of community living. Concentration of services for high-risk patients within a single multiservice team enhances continuity and coordination of care, which improves the quality of care. ACT can reduce length of hospitalization and emergency department services, which reduces the cost of mental health treatment for patients with serious mental illnesses (Thoegersen et al., 2019).

RECOVERY-ORIENTED REHABILITATION SETTINGS

Psychiatric rehabilitation programs, also termed *psychosocial rehabilitation*, focus on the reintegration of people with psychiatric disabilities into the community through work, education, and social avenues while addressing their medical and residential needs. The goal is to empower patients to achieve the highest level of functioning possible. Therapeutic activities or interventions are provided individually or in groups. They may include development and maintenance of daily and community living skills, such as communication (basic language), vocational, self-care (grooming, bodily care, feeding), and social skills that help patients function in the community. These programs promote increased functioning with the least necessary ongoing professional intervention. Psychiatric rehabilitation provides a highly structured environment, similar to a

PHP, in a variety of settings, such as office buildings, hospital outpatient units, and freestanding structures.

The mental health nurse's role continues to focus on the consumer's recovery goals in all treatment settings. As behavioral health care delivery occurs more in outpatient settings, so does the work of nurses. Most rehabilitation programs have a full-time nurse who functions as part of the multidisciplinary team.

Psychiatric rehabilitation nurses are concerned with the recovery-oriented, holistic evaluation of the person and with assessing and educating the patient on compliance issues, necessary laboratory work, and environmental and lifestyle issues. This evaluation assesses the five dimensions of a person—physical, emotional, intellectual, social, and spiritual—and emphasizes recovery. Issues of psychotropic medication—evaluation of response, monitoring of side effects, and connection with pharmacy services—also fall to the nurse.

Self-Help Groups

Self-help groups are available in the community. These include AA, NA, and related 12-step programs. AA and NA use peer support as a strategy for helping people who are attempting to abstain from alcohol or drug use. Counseling, mentoring, and support are provided by individuals with alcohol or drug dependence who successfully abstain from substance use. In many cases, people with comorbid substance abuse and psychiatric diagnoses, such as schizophrenia and bipolar disorder, are unable to benefit from traditional AA self-help groups because of their psychiatric symptoms. For this reason, AA groups are available to meet the needs of individuals with comorbid psychiatric and substance abuse issues. Nurses may be asked to serve as consultants to these groups.

Relapse Prevention Aftercare Programs

Relapse of mental illness symptoms and substance abuse is the major reason for rehospitalization in the United States. **Relapse** is the recurrence or marked increase in severity of the symptoms of a disease, especially after a period of apparent improvement or stability. Many issues affect a person's well-being. First and foremost, patients must believe that their lives are meaningful and worthwhile. Homelessness and unemployment create tremendous threats to a

person's identity and feelings of wellness.

Much work has gone into relapse prevention programs for the major mental illnesses and addiction disorders. Relapse prevention programs involve both patients and families and seek to (1) educate them about the illness, (2) enable them to cope with the chronic nature of the illness, (3) teach them to recognize early warning signs of relapse, (4) educate them about prescribed medications and the need for compliance, and (5) inform them about other disease management strategies (i.e., stress management, exercise) in preventing relapse.

Nurses become involved in relapse prevention programs in several different ways. They can act as referral sources for the programs, trainers or leaders of the programs, or aftercare sources for patients when the programs are completed. In addition, mental health nurses can help patients and family members by promoting optimism, sticking to goals and aspirations, and focusing on individual strengths.

Supported Employment

The ability to work in a competitive job is important in recovery from severe mental illness. Supported employment services assist individuals to find work; assess individuals' skills, attitudes, behaviors, and interest relevant to work; offer vocational rehabilitation or other training; and provide work opportunities. Consumers receive onsite support and job-coaching services on a one-to-one basis. They occur in real work settings and are used for patients with severe mental illnesses. The primary focus is to maintain attachment between the mentally ill person and the work force.

ALTERNATIVE HOUSING ARRANGEMENTS

Housing is an important factor in successful community transition. Patients with psychiatric disabilities who are homeless are a vulnerable population. One of the largest hurdles to overcome in treating the persons with a mental illness is finding appropriate housing that will meet the individual's immediate social, financial, and safety needs. Caring for people with severe mental illnesses in the home can be very stressful for family members because of the person's symptom severity and unpredictable behaviors. Many individuals with a mental illness live

in some form of supervised or supported community living situation, which ranges from highly supervised congregate settings to independent apartments. The following discussion focuses on four models of alternative housing and the role of the nurse. These are personal care homes, board-and-care homes, therapeutic foster care, and supervised apartments.

Personal Care Homes

Personal care homes operate within houses in the community. Usually, 6 to 10 people live in one house with a health care attendant providing 24-hour supervision to assist with medication monitoring or other minor activities, including transportation to appointments, meals, and self-care skills. The clientele generally is heterogeneous and includes older adults, people with mild mental retardation, and patients with chronic and subacute mental illness. Most states require these homes to be licensed.

Board-and-Care Homes

Board-and-care homes provide 24-hour supervision and assistance with medications, meals, and some self-care skills. Individualized attention to self-care skills and other activities of daily living generally is not available. These homes are licensed to house 50 to 150 people in one location. Rooms are shared, with two to four occupants per bedroom.

Therapeutic Foster Care

Therapeutic foster care is indicated for patients in need of a family-like environment and a high level of support. Therapeutic foster care is available for child, adolescent, and adult populations. This level of care actually places patients in residences of families specially trained to handle individuals with mental illnesses. The training usually consists of crisis management, medication education, and illness education. The family provides supervision, structure, and support for the individual living with them. The person who receives these services shares the responsibility of completing household chores and may be

required to attend an outpatient program during the day.

Supervised Apartments

In a supervised apartment setting, individuals live in their own apartments, usually alone or with one roommate, and are responsible for all household chores and self-care. A staff member or *supervisor* stops by each apartment routinely to evaluate how well the patients are doing, make sure they are taking their medications, and ensure that the household is being maintained. The supervisor may also be required to mediate disagreements between roommates.

Role of Nurses in Alternative Housing

Professional registered nurses typically are not employed in alternative housing settings. However, nurses play a pivotal role in the successful reintegration of patients from more restrictive inpatient settings into society. Nurses are employed in PHPs and inpatient units and as case managers. Therefore, nurses act as liaisons for the residential placement of patients. Nurses are employed directly as consultants or provide consultation to treatment teams during discharge planning in determining appropriate outpatient settings, evaluating medication follow-up needs, and making recommendations for necessary medical care for existing physical conditions. Feedback from the residential care providers and follow-up by the treatment team regarding the patient's response to treatment interventions are essential. Rehospitalization can be curtailed if the residential care operators identify and forward specific problems to the treatment teams. Patient interventions can be modified in an outpatient setting.

INTEGRATED CARE

People diagnosed with psychiatric disorders frequently have complex comorbid medical illnesses, such as hypertension, cardiac disease, metabolic syndrome, and diabetes, that require regular and ongoing treatment and engagement in self-management. However, access to care for complex health problems is often very

limited in this population. Collaboration between medical and psychiatric providers is important to ensure that patients receive holistic care that addresses all illnesses. **Integrated care** is a health systems delivery model that ensures people receive a continuum of health promotion, disease management, rehabilitation, and palliative care services at different levels and settings according to their needs throughout life (World health Organization [WHO], 2015).

Medical Home

Integrated care can also be delivered in a **medical home**, a treatment setting that uses a team approach to deliver comprehensive patient-centered care that addresses all aspects of patients' health-related needs. There are five key functions of the medical home:

- comprehensive care that meets the majority of the person's physical and mental health care needs through a team-based approach
- patient-centered care that delivers primary care that is oriented toward the whole person
- coordinated care across all elements of the health care system
- accessible services through minimizing wait times, enhanced office hours, and after-hours access to providers through alternative methods such as telephone or mail
- quality and safety through providing safe, high-quality care through clinical judgment, decision support tools, evidence-based care, shared decision-making, performance measurement, improvement activities (Agency for Healthcare Quality and Research, 2020)

Health and Illness Management in the Community

High rates of medical illnesses among people with serious mental illnesses are often attributed to side effects of medication and lifestyle factors. Rates of smoking and obesity are very high among people diagnosed with posttraumatic stress disorder. They often do not engage in wellness and health promotion activities because of psychiatric symptoms, of lack of understanding of what they need to do to promote health, and their residing in unsafe communities (van der Berk-Clark et al., 2018).

Community mental health centers and therapeutic rehabilitation centers are convenient and safe settings to provide services that promote wellness in this

population. These community centers can provide health education, self-management programs, healthy eating and cooking classes, group exercise or walking programs, weight loss groups, smoking cessation counseling, and screening for medical comorbidities.

MANAGED CARE

The concept of managed care emerged in efforts to coordinate patient care efficiently and cost effectively. **Managed care organizations** provide services through health maintenance organizations or preferred provider organizations. Purchasers of health care, such as employers and government health agencies, contract with managed care organizations to provide mental health services. Traditionally, these services were separated from general medical care packages and reimbursed differently than other health care services. With the passage of the *Affordable Care Act* (see [Chapter 1](#)), the mental health services are supposed to be reimbursed at the same level as other health care problems. The recent trend is integration of many mental health services within a primary care setting. The goals of this approach to care are to increase access to care and to provide the most appropriate level of services in the least restrictive setting. Efforts focus on providing more outpatient and alternative treatment programs and avoiding costly inpatient hospitalizations. When properly conducted and administered, an integrated primary care allows patients better access to quality services while using health care dollars wisely.

Today, managed behavioral health care has succeeded in standardizing admissions criteria, reducing length of patient stay, and directing patients to the proper level of care—inpatient and outpatient—all while attempting to control the costs. Across the continuum of care nurses encounter integrated or collaborative organizations, and they must be familiar with the policies, procedures, and clinical judgment criteria established by managed care organizations. As the delivery of mental health care services becomes more integrated into primary care and growing numbers of patients with mental illnesses reach older age, increasing demands are placed on the health and mental health care systems to accommodate the needs of this population. Rates of comorbid medical illnesses are high in older adults with severe mental illnesses, and the need is great for services that provide adequate psychiatric and medical care for this population, ideally in the same treatment setting (Bartels et

al., 2018).

The Nurse's Role in Negotiating the Mental Health Delivery Systems

Because of shorter inpatient stays, inpatient psychiatric–mental health nurses maximize the short time they have by educating patients about their illness, available community resources, and medications to minimize the potential for relapse. These nurses focus on teaching social skills and self-reliance and creating empowering environments that in turn build self-confidence and help the patient move toward recovery.

The interface of psychiatric–mental health nurses with other nurses in managed care organizations and integrated primary care systems is primarily in the form of communicating the progress of individual patients to the nurses (mental health and nonmental health) and other health care workers who maintain a long-term relationship with the patient and family.

Public and Private Collaboration

Today, there are many public–private sector collaborations. The need for public–private collaboration prompted the National Association of State Mental Health Program Directors, an organization representing the 55 state and territorial public mental health systems, and the American Managed Behavioral Healthcare Association, an organization representing private managed behavioral health care firms, to work together. Nurses can expect to see more strategic alliances and joint ventures between the public and private sectors.

NURSING PRACTICE IN THE CONTINUUM OF CARE

Throughout this chapter, nurses' roles in different settings have been explained. Regardless of the situation or setting, nurses conduct assessments at the point of first patient contact. The individual's needs are then matched with the most

appropriate setting, service, or program that will meet those needs. If a patient is admitted for services, the nurse also begins discharge planning upon first admission.

Assessment and Identification of Services

Choosing the level of care begins with an initial assessment to determine the need for care, the type of care to be provided, and the need for additional assessment. The nurse must discuss with the patient with suicidal and homicidal thoughts. Nurses also need to consider financial issues because funding considerations may play a part in placement options. Other factors affecting the selection of care include the type of treatment the individual seeks, their current physical condition and ability to consent to treatment, and the organization's ability to provide direct care or to deflect care to another service provider.

Based on the results of the initial assessment, the nurse may admit the patient into services provided at that agency or initiate a referral or transfer to provide the intensity and scope of treatment required by the individual at that point in time ([Fig. 5.1](#)). Referral involves sending an individual from one clinician to another or from one service setting to another for care or consultation. Transfer involves formally shifting responsibility for the care of an individual from one clinician to another or from one care unit to another. The processes of referral and transfer to other levels of care are integral for effective use of services along the continuum. These processes are based on the individual's assessed needs and the organization's capability to provide the care. [Figure 5.1](#) depicts the process of assessment, treatment, transfer, and referral when considering appropriate levels of care.

Discharge Planning

Discharge planning begins upon admission of the individual to any level of health care. Most facilities have a written procedure for discharge planning. This procedure often provides for a transfer of clinical care information when a person is referred, transferred, or discharged to another facility or level of care. All discharge planning activities should be documented in the clinical record, including the patient's response to proposed aftercare treatment, follow-up for

psychiatric and physical health problems, and discharge instructions. Medication education, food–drug interactions, drug–drug interactions, and special diet instructions (if applicable) are extremely important in ensuring patient safety. Discharge planning is an integral part of psychiatric nursing care and should be considered a part of the psychiatric rehabilitation process. In addressing an individual’s needs, one can coordinate aftercare and discharge interventions for optimal outcomes. The overall goal of discharge planning is to provide the patient with all of the resources they need to function as independently as possible in the least restrictive environment and to avoid rehospitalization.

The nurse can optimize discharge plan compliance by partnering with the patient from the first encounter. Because patients with mental illnesses may have limited cognitive abilities and residual motivational and anxiety problems, the nurse should explain in detail all aftercare plans and instructions to the patient. It is helpful also to schedule all aftercare appointments before the patient leaves the facility. The nurse should then give the patient written instructions about where and when to go for the appointment and a contact person’s name and telephone number at the aftercare placement. Finally, the nurse should review emergency telephone numbers and contacts and medication instructions with the patient.

SUMMARY OF KEY POINTS

- The continuum of care is a comprehensive system of services and programs designed to match the needs of the individual with the appropriate treatment in settings that vary according to levels of service, structure, and intensity of care.
- Psychiatric–mental health nurses’ specific responsibilities vary according to the setting. In most settings, nurses function as members of a multidisciplinary team and assume responsibility for assessment and selection of level of care, education, evaluation of response to treatment, referral or transfer to a more appropriate level of care, and discharge planning. Discharge planning provides patients with all the resources they need to function effectively in the community and avoid rehospitalization.
- Mental health care can be given within an integrated primary care setting or a

separate system. The nurse's role will vary depending upon the setting and the needs of the patient.

CRITICAL THINKING CHALLENGES

1. Define the continuum of care in mental health care and discuss the importance of the least restrictive environment.
2. Differentiate the role of the nurse in each of the following continuum settings:
 - a. Crisis stabilization
 - b. In-home detoxification
 - c. Partial hospitalization
 - d. Assertive community treatment
3. Compare alternative housing arrangements, including personal care homes, board-and-care homes, therapeutic foster care, and supervised apartments.
4. Envision using more than one service at a time. What combinations of services could benefit patients and families?
5. Identify the specific community mental health service needs of patients across the lifespan. Include the unique needs of children, adolescents, adults, and older patients. How do community mental health services meet these needs?

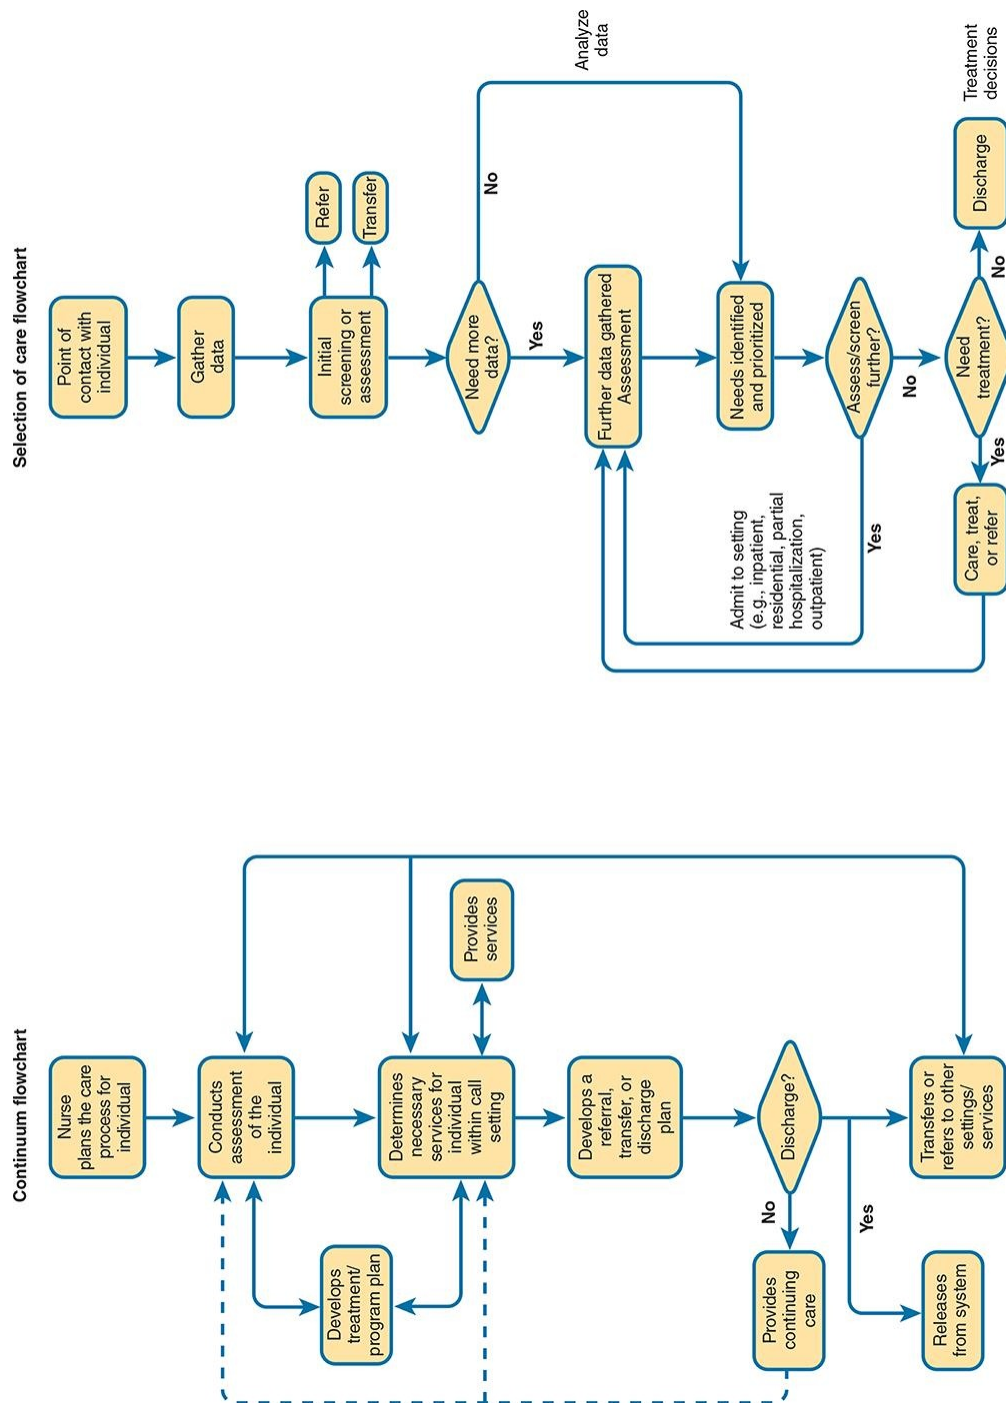

Figure 5-1: Flowcharts illustrating nursing care in the mental health care continuum and selection of care.

Unit II: Foundations of Psychiatric Nursing

6

Ethics, Standards, and Nursing Frameworks

Valerie Yancey and Mary Ann Boyd

KEYCONCEPTS

- biopsychosocial framework
- ethical principles
- standards of practice

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Describe the importance of the ethical principles of beneficence, fidelity, justice, nonmaleficence, respect for autonomy, and veracity for considering ethical situations in psychiatric–mental health (PMH) nursing practice.
2. Delineate the scope and standards of PMH nursing practice.
3. Describe how professional nursing organizations influence and strengthen PMH nursing practice.
4. Discuss the relationship between the biopsychosocial model and wellness and recovery models used as frameworks for PMH nursing practice.
5. Identify the basic tools used in PMH nursing practice.
6. Discuss emerging challenges for PMH nursing.
7. Discuss the benefits of using standardized nursing languages.

KEY TERMS

- Beneficence
 - Clinical judgment
 - Fidelity
 - Justice
 - Nonmaleficence
 - Nursing process
 - Paternalism
 - Psychiatric–mental health advanced practice registered nurse
 - Psychiatric–mental health registered nurse
 - Reflection
 - Respect for autonomy
 - Scope and standards of practice
 - Standardized nursing language
 - Veracity
-

INTRODUCTION

This chapter opens with a discussion of the ethical principles used by psychiatric nurses daily. The scope and standards of practice are then highlighted. This chapter explains how the biopsychosocial model provides a framework for psychiatric–mental health (PMH) nursing and relates to recovery and wellness models. A discussion of the challenges facing PMH nursing helps create a vision for the changing nature of this dynamic nursing specialty.

ETHICS OF PSYCHIATRIC NURSING

PMH nursing practice is guided by the *Code of Ethics for Nurses with Interpretive Statements* ([Box 6.1](#)). The *Code* communicates nursing’s ethical values, obligations, duties, and professional ideals; establishes ethical standards; and confirms the profession’s commitment to society (American Nurses Association [ANA], 2015). When faced with ethical concerns, the nurse can reflect on a series of questions, outlined in [Box 6.2](#).

BOX 6.1

Code of Ethics for Nurses

1. The nurse practices with compassion and respect for the inherent dignity, worth, and unique attributes of every person.
2. The nurse’s primary commitment is to the patient, whether an individual, family, group, or community.
3. The nurse promotes, advocates for, and protects the rights, health, and safety of the patient.
4. The nurse has authority, accountability, and responsibility for nursing practice; makes decisions; and takes action consistent with the obligation to promote health and to provide optimal care.
5. The nurse owes the same duties to self as to others, including the responsibility to promote health and safety, preserve wholeness of character and integrity, maintain competence, and continue personal and professional growth.
6. The nurse, through individual and collective effort, establishes, maintains, and improves the ethical environment of the work setting and conditions of employment that are conducive to safe, quality health care.
7. The nurse, in all roles and settings, advances the profession through research and scholarly inquiry, professional standards development, and the generation of both nursing and health policy.
8. The nurse collaborates with other health professionals and the public to protect human rights, promote health diplomacy, and reduce health disparities.

- d. The profession of nursing, collectively through its professional organizations, must articulate nursing values, maintain the integrity of the profession, and integrate principles of social justice into nursing and health policy.

BOX 6.2

Basic Questions for Ethical Decision-Making

- What do I know about this patient situation?
- What do I know about the patient's values and moral preferences?
- What assumptions am I making that need more data to clarify?
- What are my own feelings (and values) about the situation, and how might they be influencing how I view and respond to this situation?
- Are my own values in conflict with those of the patient?
- What else do I need to know about this case, and where can I obtain this information?
- What can I never know about this case?
- Given my primary obligation to the patient, what should I do to be ethical?

Reprinted with permission from Davis, A. (2008). Provision two. In M. Fowler (Ed.), *Guide to the code of ethics for nursing: Interpretation and application* (p. 18). [Nursebooks.org](https://nursebooks.org).

Four primary health care **ethical principles**—respect for autonomy, beneficence, nonmaleficence, and justice—guide nurses' consideration of ethical concerns. In health care decisions and conduct, these principles highlight the ethical aspects of the patient situations, decision dilemmas, and relationships.

The principle of **respect for autonomy** is based on the understanding that each person has the fundamental right to make voluntary decisions about their health care and life decisions. Persons are to be regarded as self-determining. The principle of respect for autonomy gives rise to expectations for ethical conduct, namely, the use of informed consent in health care practices. To give consent to a treatment or procedure, a person must have the needed relevant information, be able to rationally deliberate, and not be forced into a decision. The PMH nurse protects autonomy by assessing a person's decisional capacity to act in their own best interests as they see it. Nurses are also obligated by the

principle of respect for autonomy to protect individuals' privacy. A person loses the ability to be self-determining if information about their health conditions is shared with others without permission. Privacy can be important especially in mental health practice because of the potential for stigmatization and the patient's potential vulnerability. The meaning of the principle of **beneficence** (goodness) rests on the assumption that professionals have a duty to act in ways that benefit a patient or community, and that they take steps necessary to minimize harm. The scope and standards of nursing practice (discussed later in this chapter) delineate the ways that nurses are to act in a beneficent way toward those in their care. Nurses use their knowledge and skills to create environments in which people can thrive. **Nonmaleficence** is the duty one has to never intentionally harm another. Often in health care decisions, negative outcomes may occur as a result of any choice that is made. The professional is obligated to minimize the harm and risks as much as possible for both the individual and others who may be involved. The principle of **justice** encourages providers to consider how the goods of a society, including health care, are distributed. As noted in the first provision of the *Code of Ethics for Nurses*, providers have an ethical duty to treat all people with dignity, respect, and fairness. Those "goods" are to be distributed equally. All people should have access to health care. Justice also requires that we consider instances when basic goods should be distributed so that those who need more get what they need for health and survival, even if they use more resources than others get. Mental health services are often not readily available to those most in need, a violation of the principle of justice.

Each of the four primary principles prompts nurses to focus on different aspects of an ethical decision or relationship. Sometimes, one principle may be in tension with one or more of the other principles. For example, a patient may decide to stop taking a medication (autonomy), but the nurse wants to avoid the harm that could likely come to the patient or others when the patient discontinues medication use. In ethical dilemmas, all of the principles are important and relevant. The PMH nurse must be able to weigh the relative merits of the principles when there is a conflict and help others to see the competing ethical claims. The nurse strives to promote a decision that achieves the most good and avoids harm as much as possible.

NCLEXNOTE Be prepared to think of patient situations that illustrate the principles of respect for autonomy and beneficence and identify how patients' and nurses' views may differ.

Two secondary ethical principles, veracity and fidelity, provide additional guidance for mental health care practice. **Veracity** highlights one's duty to tell the truth. Nurses guided by the principle of veracity understand that honesty provides a foundation for the development of trust in a helping, healing relationship. There are times, however, when "telling the truth" requires judgment and sensitivity to the patient's situation. For example, giving others more information than is necessary, even if that information is true, could cause an excess of fear, anxiety, and harm. Or, there may be times when the nurse cannot truthfully respond to a patient's question. A nurse cannot guarantee or truthfully assure a patient that a medication will eliminate all mental health symptoms. Nurses use good moral reasoning and judgment when they consider how to be truthful, using the principle of beneficence (doing the good) in their responses to others. **Fidelity** implies that nurses should be faithful to their obligations and duties toward others, society, and the nursing profession. Fidelity is also essential for the maintenance of trusting relationships because it is centered on doing what one says will be done (keeping promises). At times, health care professionals use the principle of **paternalism** to guide their actions and decisions. The paternalism is based on the belief that professionals have the knowledge and education needed to make decisions for others and should do so. Often professionals' expert knowledge of the technical and medical aspects of a situation makes their judgment most valuable. Professionals may not know, however, the details of a person's life and values. Nurses protect against unwarranted use of a paternalistic approach by encouraging patient, family, and community involvement in decisions. Paternalism may be justified in some mental health conditions in which a person is temporarily unable to deliberate in the best interests of self or others. Socially, some health care decisions, such as the mandated use of seat belts or motorcycle helmets, are made paternalistically to protect others. Paternalism can be in direct conflict with the mental health recovery belief of self-determination (see [Chapters 1 and 7](#)).

NCLEXNOTE Be able to identify ethical situations encountered by psychiatric–mental health nurses in inpatient and outpatient settings.

SCOPE AND STANDARDS OF PRACTICE

The legal authority to practice nursing is regulated by law and granted by each state or province. The **scope and standards of practice** are defined by the nursing profession and describe the responsibilities to which nurses are legally, professionally, and ethically held accountable.

The American Nurses Association (ANA) and psychiatric nursing organizations (discussed later in this chapter) further clarify the boundaries of PMH nursing and establish the scope of practice for nurses at different educational levels and in various nursing roles. Nurses are ethically obligated to abide by the scope and standards of practice to honor their commitments made to patients, communities, and society.

Scope of Psychiatric–Mental Health Nursing

PMH nurses address a wide range of actual and potential mental health problems or psychiatric disorders, including emotional stress or crisis, self-concept changes, addictive patterns, developmental issues, physical symptoms that occur with psychological changes, and mental health and treatment symptom management. To understand an individual's mental health condition and select appropriate interventions, nurses integrate knowledge from the biologic, psychological, and social domains.

KEYCONCEPT Six **standards of practice** define the parameters of PMH nursing and are organized according to the nursing process steps: assessment, diagnosis, outcome identification, planning, implementation, and evaluation ([Box 6.3](#)).

Standards of Practice

The **nursing process** serves as a framework for clinical judgment decision-making and nursing practice.

BOX 6.3

Standards of Practice

STANDARD 1: ASSESSMENT

The PMH-RN collects and synthesizes comprehensive health data that are pertinent to the health care consumer's health and/or situation.

STANDARD 2: DIAGNOSIS

The PMH-RN analyzes the assessment data to determine diagnoses, problems, and areas of focus for care and treatment, including level of risk.

STANDARD 3: OUTCOMES IDENTIFICATION

The PMH-RN identifies expected outcomes and the health care consumer's goals for a plan individualized to the health care consumer or to the situation.

STANDARD 4: PLANNING

The PMH-RN develops a plan that prescribes strategies and alternatives to assist the health care consumer in attainment of expected outcomes.

Standard 5: Implementation

The PMH-RN implements the specified plan.

Standard 5A: Coordination of Care

The PMH-RN coordinates care delivery.

Standard 5B: Health Teaching and Health Promotion

The PMH-RN employs strategies to promote health and a safe environment.

Standard 5C: Consultation

The PMH-APRN provides consultation to influence the identified plan, enhance the abilities of other clinicians to provide services for health care consumers, and effect change.

Standard 5D: Prescriptive Authority and Treatment

The PMH-APRN uses prescriptive authority, procedures, referrals, treatments, and therapies in accordance with state and federal laws and regulations.

Standard 5E: Pharmacologic, Biologic, and Integrative Therapies

The PMH-APRN incorporates knowledge of pharmacologic, biologic, and complementary interventions with applied clinical skills to restore the health care consumer's health and prevent further disability.

Standard 5F: Milieu Therapy

The PMH-APRN provides, structures, and maintains a safe, therapeutic, recovery-oriented environment in collaboration with health care consumers, families, and other health care clinicians.

Standard 5G: Therapeutic Relationship and Counseling

The PMH-RN uses the therapeutic relationship and counseling interventions to assist health care consumers in their individual recovery journeys by improving and regaining their previous coping abilities, fostering mental health, and preventing mental disorder and disability.

Standard 5H: Psychotherapy

The PMH-APRN conducts individual, couples, group, and family psychotherapy using evidence-based psychotherapeutic frameworks and the nurse–client therapeutic relationship.

STANDARD 6: EVALUATION

The PMH-RN evaluates progress toward attainment of expected outcomes.

Reprinted with permission from American Nurses Association, American Psychiatric Nurses Association, & International Society of Psychiatric–Mental Health Nurses. (2014). *Psychiatric–mental health nursing: Scope and standards of practice* (2nd ed.). [Nursesbooks.org](https://nursesbooks.org)

Each of the six standards includes competencies for a **Psychiatric–Mental Health Registered Nurse** (PMH-RN) and **Psychiatric–Mental Health Advanced Practice Registered Nurses** (PMH-APRN) practice. The fifth standard, implementation, has several subcategories that define the standards for specific interventions.

Standards of Professional Performance

Ten standards of professional performance for PMH nurses flow from the six standards of practice. The 10 standards for professional performance include ethics, education, evidence-based practice and research, quality of practice, communication, leadership, collaboration, professional practice evaluation, resource utilization, and environmental health. Each standard of performance includes expected competencies ([Table 6.1](#)) (American Nurses Association, American Psychiatric Nurses Association, & International Society of Psychiatric–Mental Health Nurses, 2014).

Levels of Practice

There are two levels of PMH nursing practice. The first level is the PMH-RN whose educational preparation is at the bachelor's or associate's degree level. The PMH-APRN receives educational preparation at the master's or doctoral level. A PMH-APRN can practice as a psychiatric–mental health clinical nurse specialist or as a psychiatric–mental health nurse practitioner ([Box 6.4](#)).

Psychiatric–Mental Health Nursing Practice

According to the *Psychiatric–Mental Health Nursing: Scope and Standards of Practice*, the PMH nurse is a registered nurse who demonstrates specialized competence and knowledge, skills, and abilities in caring for persons with

mental health issues and problems and psychiatric disorders. Competency is obtained through education and experience. The preferred educational preparation for a PMH-RN is at the baccalaureate level, with 59 credentialing by the American Nurses Credentialing Center or a recognized certification organization (ANA et al., 2014).

TABLE 6.1 STANDARDS OF PROFESSIONAL PERFORMANCE

Standard	Area of Performance	Description
7	Ethics	Integrates ethical provisions in all areas of practice.
8	Education	Attains knowledge and competency that reflect current nursing practice.
9	Evidence-based practice and research	Integrates evidence and research findings into practice.
10	Quality of practice	Systematically enhances the quality and effectiveness of nursing practice.
11	Communication	Communicates effectively in a variety of formats in all areas of practice.
12	Leadership	Provides leadership in the professional practice setting and the profession.
13	Collaboration	Collaborates with the health care consumer, family, interprofessional health team, and others in the conduct of nursing practice.
14	Professional practice evaluation	Evaluates one's own practice in relation to the professional practice standards and guidelines, relevant statutes, rules, and regulations.
15	Resource utilization	Considers factors related to safety, effectiveness, cost, and impact on practice in the planning and delivery of nursing services.
16	Environmental health	Practices in an environmentally safe and healthy manner.

Reprinted with permission from American Nurses Association, American Psychiatric Nurses Association, & International Society of Psychiatric–Mental Health Nurses. (2014). *Psychiatric–mental health nursing: Scope and standards of practice* (2nd ed.). [Nursesbooks.org](http://nursesbooks.org).

BOX 6.4

Clinical Activities of Psychiatric–Mental Health Nurses

PSYCHIATRIC–MENTAL HEALTH REGISTERED NURSE

- Health promotion and health maintenance
- Intake screening, evaluation, and triage
- Case management
- Provision of therapeutic and safe environments
- Milieu therapy
- Promotion of self-care activities
- Administration of psychobiologic treatment and monitoring responses
- Complementary interventions
- Crisis intervention and stabilization
- Psychiatric rehabilitation

ADVANCED PRACTICE REGISTERED NURSE

- Psychopharmacologic interventions
- Psychotherapy
- Community interventions
- Case management
- Program development and management
- Clinical supervision
- Consultation and liaison

PMH-RNs are “characterized by the use of the nursing process to treat people with actual or potential mental health problems, psychiatric disorders and co-occurring psychiatric and substance use disorders” (ANA et al., 2014, p. 25). By using the nursing process, the PMH-RN promotes and fosters health and safety, assesses dysfunction and areas of strength, and assists individuals in achieving personal recovery goals. The nurse performs a wide range of interventions, including health promotion and health maintenance strategies, intake screening and evaluation and triage, case management, milieu therapy, promotion of self-care activities, psychobiologic interventions, complementary interventions, health teaching, counseling, crisis care, and psychiatric rehabilitation. An overview of psychiatric nursing interventions is provided in [Unit 3](#).

Psychiatric–Mental Health Advanced Practice Registered Nurse

The PMH-APRN, a licensed registered nurse educationally prepared at the master's or doctoral level, is nationally certified as a clinical nurse specialist or a psychiatric nurse practitioner by the American Nurses Credentialing Center. A PMH-APRN educated in a Doctor of Nursing program focuses on nursing practice knowledge development, quality improvement, action research, health systems leadership, and health policy. Nurses with doctoral preparation at the Doctor of Philosophy level focus on the development of nursing science and acquire skills in designing, conducting, and analyzing research. Doctor of Nursing Science degrees, offered at some universities, have a research focus. Nurse administrators and educators, depending on setting and role requirements, can be PMH-RNs, or APRNs.

Psychiatric–Mental Health Nursing Organizations

Nursing professional organizations provide leadership and give legitimacy and definition to PMH nursing. They advocate for nurses to function within the fullest extent of their professional scope of practice and provide health policy advocacy at local, state, and national levels. 60The ANA, nursing's largest organization, fosters high standards of practice, promotes safe and ethical work environments for nurses, and advocates for needed health care policy and legislation. The ANA supports and advocates for PMH nursing practice at national and state levels and works closely with PMH nursing organizations.

Two organizations for psychiatric nurses, the American Psychiatric Nurses Association (APNA) and the International Society of Psychiatric Nursing (ISPN), focus on the specific interests of PMH care and nursing practice. The APNA, the largest PMH nursing organization, advances PMH nursing practice and helps shape mental health policy thereby improving mental health care for culturally diverse individuals, families, groups, and communities. The ISPN consists of four specialist divisions: the Association of Child and Adolescent Psychiatric Nurses, International Society of Psychiatric Consultation Liaison Nurses, Society for Education and Research in Psychiatric–Mental Health Nursing, and Adult and Geropsychiatric–Mental Health Nurses. The ISPN unites and strengthens PMH nurses and promotes quality care for individuals and families experiencing mental health problems. The International Nurses Society on Addictions is committed to the prevention, intervention, treatment, and management of addictive disorders. These organizations have annual meetings at

which new research is presented. Student memberships are available.

THE BIOPSYCHOSOCIAL FRAMEWORK

The biopsychosocial framework (Fig. 6.1) is a well-recognized, holistic model for organizing nursing practice. Each of the model's three domains—biologic, psychological, and social—has an independent knowledge and treatment focus but interacts and is mutually interdependent with the other domains. Each domain (described in the following section) influences an individual's mental health and provides a framework for implementing the nursing process.

A nurse using a biopsychosocial framework assesses a patient's physical, psychological, and social strengths and needs and considers the interaction of those three domains in making a nursing diagnosis. The biopsychosocial framework is congruent with the recovery and wellness models and guides recovery-oriented care (see Chapter 1). Standardized nursing languages, such as the International Classification for Nursing Practice, Clinical Care Classification, and the Omaha System, can be used with this framework (da Cruz Sequeira & Sampaio, 2018; Kerr et al., 2016; Saba, 2018).

KEYCONCEPT The **biopsychosocial framework** consists of three separate but interdependent domains: biologic, psychological, and social. Each domain has an independent knowledge and treatment focus but interacts and is mutually interdependent with the other domains.

FIGURE 6.1 The biopsychosocial model.

Biologic Domain

The *biologic* domain is concerned with the physiological aspects of all health conditions, including the biologic aspects of mental health conditions or disorders. Biologic theories and concepts consider vital functional health patterns, essential when assessing a person's mental health: exercise, elimination patterns, sleep, and nutrition. Neurobiologic theories serve as a basis for understanding and administering pharmacologic agents (see [Chapters 8](#) and [12](#)).

Psychological Domain

The *psychological* domain involves the theoretical basis of the psychological processes—thoughts, feelings, and behavior (intrapersonal dynamics) that influence one's emotion, cognition, and behavior. Psychological and nursing sciences generate theories and research critical to a nurse's understanding and assessment of patients' mental health symptoms and responses to treatment. Although some mental disorders have a neurobiological basis, symptoms are experienced and observed as psychological. For example, even though manic behavior is caused by dysfunction in the brain, there are no laboratory tests to confirm a diagnosis, only a pattern of behavior.

PMH nurses use many behavioral interventions, including cognitive approaches, behavior therapy, and patient education. In using therapeutic communication and in developing therapeutic relationships, a nurse should have self-awareness and the capacity to be aware of and interpret a patient's feelings, psychological states, and behaviors (see [Chapter 10](#)).

Social Domain

The *social* domain includes theories that describe the influence of social forces on the patient, family, and community within cultural settings. Social and nursing sciences illustrate how social connections within families and communities influence mental health, treatment, and recovery. Psychiatric

disorders are not caused solely by social factors, but their mental health manifestations and treatment can be significantly affected by the society in which a patient lives. For example, the presence of social and family support often improves treatment outcomes. Moreover, families of origin, extended families, or other significant relationships can positively influence or complicate a patient's mental health condition and treatment outcomes. Community forces, including cultural and ethnic groups within larger communities, shape the patient's manifestation of disorders, response to treatment, and overall view of mental illness.

TOOLS OF PSYCHIATRIC NURSING PRACTICE

Self

The most important tool of psychiatric nursing is the self. Through relationship building, patients learn to trust the nurse who then guides, teaches, and advocates for quality care and treatment. This text emphasizes the primary importance of the patient–nurse relationship.

BOX 6.5

Research for Best Practices: Practice Development Strategies

Cheng, S., Backonja, U., Buck, B., Monroe-DeVita, M., & Walsh, E. (2020). Facilitating pathways to care: A qualitative study of the self-reported needs and coping skills of caregiver of young adults diagnosed with early psychosis. *Journal of Psychiatric and Mental Health Nursing*, 27(4), 368–379. <https://doi.org/10.1111/jpm.12591>

THE QUESTION: What is the lived experience of family members of a young adult newly diagnosed with psychosis? What do family members with no prior experience with a serious mental health issue want to know to be better prepared to offer support and help to a family member?

METHODS: This qualitative study used focus groups to gather information about family members' lived experiences, fears, knowledge deficits, and uncertainties in providing in-home care to a young adult with new onset of psychosis. The researchers used what they learned from the focus groups to propose strategies for the use of mobile and online technologies to enhance family coping.

FINDINGS: Family members needed more information about early psychotic symptoms, symptom monitoring, resources, access to care and hospitalization, and how to maintain safety for the patient and themselves. Focus group participants expressed a desire to educate others in the public with

whom young adults interact about the symptoms of early psychotic episodes and agreed that mobile and online technologies were helpful coping devices.

IMPLICATIONS FOR NURSING: PMH nurses provide care for patients and family caregivers, knowing that positive patient outcomes depend significantly on caregiver coping and strengths. Especially early in the process of learning how to support a person with mental illness, family members need innovative approaches that address their specific needs for support and information.

Clinical Judgment and Reflection

Sound **clinical judgment** depends on critical thinking skills and reflection. Using the critical thinking skills of problem-solving and decision-making, nurses analyze, evaluate, explain, infer, and interpret biopsychosocial data. Some critical thinking activities such as nursing assessments occur in an orderly fashion, over a predictable period of time. Some decisions based on critical thinking must occur in response to an emergency or are made moment to moment, such as deciding whether a patient can leave a unit or whether a patient should receive a medication. Critical thinking is an ongoing process that undergirds safe, ethical, and effective PMH nursing care ([Box 6.5](#)).

Reflection involves ongoing self-evaluation through observing, monitoring, and judging of one's own and others' behaviors with the goal of providing effective and meaningful nursing care. Reflective skills are used to enhance all aspects of PMH nursing practice, including self-awareness, nurse–patient interactions, and evaluating systems of care.

Interdisciplinary Care

The PMH nurse collaborates with other professionals, patients, and family members in all settings. In the hospital, a patient may see a psychiatrist or psychiatric nurse practitioner who treats the symptoms and prescribes the medication; a case manager who coordinates care; a psychiatric social worker for individual psychotherapy; a 62psychiatric nurse for management of responses related to the mental disorder, administration of medication, and monitoring side effects; and an occupational therapist for transition into the workplace. In the community clinic, a patient may meet weekly with a therapist, monthly with a mental health provider who prescribes medication, and twice a

week with a group leader in a day treatment program. An interdisciplinary group of professionals bring specialized skills to the patient's care.

Plan of Care

As with patients receiving treatment for a physical condition, patients receiving PMH services also have written plans of care. The patient and family (if appropriate) should participate in the development of the plan. In situations where nurses are the primary caregivers, as in-home care, a nursing care plan is used. When professionals from other disciplines provide services to the same patient, as in a hospital or outpatient treatment facility, an interdisciplinary treatment plan may be used with or instead of a traditional nursing care plan. When an interdisciplinary plan is used, nurses should make sure the nursing components of the plan are easily identified and take responsibility for implementation and team input. The nurse provides care within the PMH nurse's scope of practice, so a traditional nursing care plan may or may not be used, depending on institutional policies.

Both nursing care plans and interdisciplinary treatment plans are individualized, based on the patient's needs and strengths. At times, third-party payers, who reimburse the costs of the service, review and approve the plan. This text places an emphasis on developing nursing care plans because they serve as a basis of nursing practice and can also be used in a multidisciplinary or interdisciplinary individual treatment plan.

CHALLENGES OF PSYCHIATRIC NURSING

The challenges of PMH nursing are increasing. New knowledge is being generated, technology has radically transformed health care, and nursing practice is becoming more specialized, evidence based, and autonomous. This section discusses some of these challenges.

Knowledge Development, Dissemination, and

Application

Knowledge is rapidly expanding in the PMH field. Genetic research has opened new areas of investigation into the etiology of several disorders such as schizophrenia, bipolar disorders, dementia, and autism and in drug dosing and metabolism. The science of psychoneuroimmunology investigates the inseparable connections among a person's psychological state, immune system, and the nervous system. Consistent with the biopsychosocial model, psychoneuroimmunology encourages PMH nurses to think holistically about mental health conditions and treatment. Understanding the influence on mental health of comorbid medical conditions—for example, hypertension, hypothyroidism, hyperthyroidism, and diabetes mellitus—contributes to the expansion of the nurses' necessary knowledge base. Psychiatric nurses must stay abreast of the advances in genetic science, psychoneuroimmunology, and comorbid disease states and incorporate into practice the most recent evidence-based findings and research to provide safe, competent care to individuals with mental disorders. Accessing new information through journals, electronic databases, and continuing education takes time and vigilance but provides a sound basis for application of new knowledge.

Overcoming Stigma

All nurses, based on their knowledge and adherence to the professional code of ethics, play an important role in dispelling myths and stigma often associated with mental illness. Stigma often prevents individuals from seeking help for mental health problems and is a form of injustice (see [Chapter 2](#)). PMH nurses have a unique insight into the harms caused by stigmatization. The principle of beneficence underlies the nurse's responsibility to reduce the burden of mental illness by addressing stigma, improving access to care, and educating patients, family members, communities, and society about the etiology, symptoms, and treatment of mental illnesses.

Holistic Nursing Care

PMH nursing has long been viewed as different and set apart from the practice

of nurses in medical and surgical settings. PMH nurses’ practice is now shaped by a holistic, comprehensive understanding of the people and communities in their care, as nurses consider the physical, psychological, spiritual, and social dynamics that influence mental health. PMH nurses accept the challenge of including mental health promotion and wellness approaches as part of their professional obligation.

Health Care Delivery System Challenges

PMH nurses face challenges posed by the systems in which mental health care is provided. Mental health care now features integrated community-based services where culturally competent, high-quality nursing care is needed ⁶³to meet the mental health care needs of patients and communities. In caring for patients who require social welfare support—housing, job opportunities, welfare, or transportation—nurses need to know how to navigate those systems to help the patient get needed assistance. Addressing the social problem can help alleviate mental health stressors and chronic illness exacerbations. Sometimes, the nurse is the only person with an understanding of medical conditions such as human immunodeficiency virus, acquired immunodeficiency syndrome, and other somatic health problems, drawing on the nurse’s teaching and mentoring skills. Despite some of the increased challenges to PMH practice in outpatient settings, assertive community treatment reduces inpatient service use, promotes continuity of outpatient care, and increases the stability of people with serious mental illnesses (see [Chapter 10](#)). Nurses are challenged to expand their knowledge and help move the currently fragmented health care system toward one focusing on patients and community-centered care.

TABLE 6.2 **EXAMPLES OF THE RELATIONSHIP OF THE BIOPSYCHOSOCIAL MODEL TO STRUCTURED NURSING LANGUAGES**

Nursing Language	Interventions		
	Biologic	Psychological	Social
Clinical Care Classification	Care related to	Teach sleep	Manage sleep

<i>Diagnosis:</i> Sleep pattern disturbance	improving pattern of sleep.	pattern control.	pattern control.
Omaha System <i>Diagnosis:</i> Insomnia	Take medication therapy as prescribed.	Establish routine. Use guided imagery.	Use community resources.

Adapted from Saba, V. K. (2018). *Clinical care classification (CCC) system. A guide to nursing documentation*. Springer Publishing Company; Martin, K. S. (2005). *The Omaha System: A key to practice, documentation, and information management* (2nd ed.). Elsevier Saunders.

The Challenges of Technology in Health Care

Technologic advances have had an unprecedented impact on health care, posing challenges to PMH nurses. The electronic storing and sharing of health records, increased use of video conferences and telehealth appointments for patient psychological assessments and therapy sessions, and the advent of technologies to track patients' medications compliance pose potential threats to patient privacy and self-determination. Nurses accept the challenge of protecting patients' medical information and have a duty to minimize any mismanagement of technology that can cause harm.

Electronic documentation has been helpful in making readily available the use of standardized nursing terminologies. Nurses improve patient care by using **standardized nursing language** when communicating with nurses and other disciplines, giving visibility to nursing activities, enhancing data collection, communicating outcome evaluations, and documenting adherence to standards of care.

There are several terminology sets being evaluated for use in electronic records (MBL Technologies, & Clinovations, 2017). [Table 6.2](#) provides an example of how some of these standardized languages relate to the biopsychosocial framework. These terminologies vary in their scope of practice and their applicability to psychiatric nursing practice. For example, the International Classification for Nursing Practice[®] is more inclusive of mental health phenomena than the Perioperative Nursing Data Set. To be useful in psychiatric nursing, standardized languages must specifically address responses to mental disorders and emotional problems.

KEYCONCEPT A **standardized nursing language** is readily understood by all nurses to describe care. It provides a common means of communication.

Professionals use telemedicine in many ways from communicating with remote sites to completing educational programs. Patients and family members often use internet access to learn about their disorders and treatment and locate resources. Persons with cognitive dysfunction benefit from software programs designed to accommodate cognitive deficits.

SUMMARY OF KEY POINTS

- The ANA's code of ethics establishes the ethical standards used by nurses in all areas of practice and communicates those standards to others.
- Several primary and secondary ethical principles provide guidance to PMH nurses for making ethical decisions and forming trusting, healing relationships with patients.
- *Psychiatric–Mental Health Nursing: Scope and Standards of Practice* (2014) establishes the areas of concern, standards of practice (using the nursing process), and standards of professional performance for basic and advanced practice nurses.
- 64Professional nursing organizations, such as the ANA, APNA, ISPN, and International Nurses Society on Addictions, provide leadership in shaping mental health care and advocate for patients and nurses.
- The biopsychosocial framework focuses on three separate but interdependent dimensions—biologic, psychological, and social—used in the assessment and treatment of mental disorders. This comprehensive and holistic framework provides the foundation for effective PMH nursing practice and is consistent with the principles of recovery and wellness models.
- Nursing care plans and interdisciplinary treatment plans are developed for each patient. Nurses use clinical reasoning skills to develop and revise plans of care.
- The PMH nurse collaborates with other disciplines to develop plans of care and often coordinates care delivery.

- Emerging challenges face PMH nurses as they incorporate advances in genetics, integrated models, evidence-based practice, and research findings into the care of persons with psychiatric disorders.
- As PMH nurses become more established as leaders in community-based health care, their roles will expand and evolve.

Unfolding Patient Stories: Linda Waterfall

Linda Waterfall, a 48-year-old Native American with an aggressive form of breast cancer, is scheduled for a mastectomy. She is extremely nervous, refusing the preoperative medication, lorazepam, and reconsidering her family's request to meet with tribal healers. How can the code of ethics for nurses be applied to ethical issues identified in this situation? What values and beliefs of a nurse might conflict with Linda's? How does understanding the differences in values influence the nurse's response to Linda's beliefs and inform ethical decision-making?

CRITICAL THINKING CHALLENGES

1. A nurse is asked to witness a wedding for two patients (one with schizophrenia and the other with bipolar disorder) who recently met while being hospitalized. They are grateful to the nurse for their care. Discuss which ethical principles apply and may be in conflict.
2. Describe how the values represented in each of the primary ethical principles help in ethical deliberations and consider how they might be in tension or conflict in some situations.
3. Describe how social conditions—environment, safety, access to resources, job opportunities, and housing—may influence a person's mental health and recovery.
4. Visit the ANA's website for a description of the certification credential requirements for PMH nursing. Compare the functions of a PMH-RN with those of an advanced practice psychiatric nurse.
5. Explain the biopsychosocial framework and apply it to the following three clinical examples:
 - a. A loud noise triggers a rapid heart rate and anxiety in a person who has recently experienced an acute traumatic event.
 - b. A teenager, depressed by social isolation, begins to eat unhealthy food.
 - c. A person with bipolar disease develops insomnia, worried that they will lose their job if someone informs the boss about their mental health diagnosis.
6. Describe how each of the following nursing organizations promotes quality mental health care and

supports nursing practice. Visit the organizations' websites to find the information you need to make comparisons.

- a. American Nurses Association
- b. American Psychiatric Nurses Association
- c. International Society of Psychiatric–Mental Health Nurses
- d. International Nurses Society on Addictions

Psychosocial Theoretic Basis of Psychiatric Nursing

Mary Ann Boyd

KEYCONCEPTS

- anxiety
- empathic linkage

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Discuss psychosocial theories that support psychiatric nursing practice.
2. Identify the underlying theories that contribute to the understanding of human beings and behavior.
3. Compare the key elements of each theory that provides a basis for psychiatric–mental health nursing practice.
4. Identify common nursing theoretic models used in psychiatric–mental health nursing.

KEY TERMS

- Behaviorism
- Classical conditioning
- Cognitions
- Cognitive theory
- Connections
- Countertransference
- Defense mechanisms
- Disconnections
- Empathy
- Family dynamics
- Formal support systems
- Informal support systems
- Interpersonal relations
- Libido
- Modeling
- Object relations
- Operant behavior
- Psychoanalysis
- Self-efficacy
- Self-system
- Social distance
- Transaction
- Transference
- Unconditional positive regard

INTRODUCTION

This chapter presents an overview of selected psychodynamic, cognitive behavioral, developmental, social, and nursing theories that serve as the knowledge base for psychiatric–mental health nursing practice. Many of these theories are covered in more depth in other chapters. Biologic theories are discussed in [Chapters 8 and 12](#).

PSYCHODYNAMIC THEORIES

Psychodynamic theories explain the development of mental or emotional processes and their effects on behavior and relationships. Many of the psychodynamic concepts and models that are important in psychiatric nursing began with the Austrian physician Sigmund Freud (1856–1939). Since his time, Freud theories have been enhanced by interpersonal and humanist models. These theories proved to be especially important in the development of therapeutic relationships, techniques, and interventions ([Table 7.1](#)).

Psychoanalytic Theory

In Freud psychoanalytic model, the human mind is conceptualized in terms of conscious mental processes (an awareness of events, thoughts, and feelings with the ability to recall them) and unconscious mental processes (thoughts and feelings that are outside awareness and are not remembered).

TABLE 7.1 PSYCHODYNAMIC MODELS

Theorist	Overview	Major Concepts	Applicability
<i>Psychoanalytic Models</i>			
Sigmund Freud(1856–1939)	Founder of psychoanalysis Believed that the unconscious could be	Id, ego, superego Consciousness Unconscious mental	Individual therapy approach used for

	accessed through dreams and free association Developed a personality theory and theory of infantile sexuality	processes Libido Object relations Anxiety and defense mechanisms Free associations, transference, and countertransference	enhancement of personal maturity and personal growth
Anna Freud (1895–1982)	Application of ego psychology to psychoanalytic treatment and child analysis with emphasis on the adaptive function of defense mechanisms	Refinement of concepts of anxiety, defense mechanisms	Individual therapy, childhood psychoanalysis

Neo-Freudian Models

Alfred Adler (1870–1937)	First defected from Freud Founded the school of individual psychology	Inferiority	Added to the understanding of human motivation
Carl Gustav Jung (1875–1961)	After separating from Freud, founded the school of psychoanalytic psychology Developed new therapeutic approaches	Redefined libido Introversion Extroversion Persona	Personalities are often assessed on the introversion and extroversion dimensions
Otto Rank (1884–1939)	Introduced idea of primary trauma of birth Active technique of therapy, including more nurturing than Freud Emphasized feeling aspect of analytic process	Birth trauma Will	Recognized the importance of feelings within psychoanalysis
Erich Fromm (1900–1980)	Emphasized the relationship of the individual to society	Society and individual are not separate	Individual desires are formed by society
Melanie Klein (1882–1960)	Devised play therapy techniques Believed that complex unconscious	Pioneer in object relations Identification	Developed different ways of applying

	fantasies existed in children younger than 6 months of age Principal source of anxiety arose from the threat to existence posed by the death instinct		psychoanalysis to children; influenced present-day English and American schools of child psychiatry
Karen Horney (1885–1952)	Opposed Freud theory of castration complex in women and his emphasis on the oedipal complex Argued that neurosis was influenced by the society in which one lived	Situational neurosis Character	Beginning of feminist analysis of psychoanalytic thought

Interpersonal Relations

Harry Stack Sullivan (1892–1949)	Impulses and striving need to be understood in terms of interpersonal situations	Participant observer Parataxic distortion Consensual validation	Provided the framework for the introduction of the interpersonal theories in nursing
----------------------------------	--	---	--

Humanist Theories

Abraham Maslow (1908–1970)	Concerned himself with healthy rather than sick people Approached individuals from a holistic-dynamic viewpoint	Needs Motivation	Used as a model to understand how people are motivated and needs that should be met
Frederick S. Perls (1893–1970)	Awareness of emotion, physical state, and repressed needs would enhance the ability to deal with emotional problems	Reality Here and now	Used as a therapeutic approach to resolve current life problems that are influenced by old, unresolved

Carl Rogers (1902–1987)	Based theory on the view of human potential for goodness Used the term <i>client</i> rather than <i>patient</i> Stressed the relationship between therapist and client	Empathy Positive regard	emotional problems Individual therapy approach that involves never giving advice and always clarifying client's feelings
-------------------------	--	----------------------------	---

Study of the Unconscious

Freud believed that the unconscious part of the human mind is only rarely recognized by the conscious, as in remembered dreams (see Movies at the end of this chapter). The term *preconscious* is used to describe unconscious material that is capable of entering consciousness.

Personality and Its Development

Freud personality structure consists of three parts: the *id*, *ego*, and *superego* (Freud, 1927). The *id* is formed by unconscious desires, primitive instincts, and unstructured drives, including sexual and aggressive tendencies that arise from the body. The *ego* consists of the sum of certain mental mechanisms, such as perception, memory, and motor control, as well as specific defense mechanisms (discussed in the following). The *ego* controls movement, perception, and contact with reality. The capacity to form mutually satisfying relationships is a fundamental function of the *ego*, which is not present at birth but is formed throughout the child's development. The *superego* is that part of the personality structure associated with ethics, standards, and self-criticism. A child's identification with important and esteemed people in early life, particularly parents, helps form the *superego*.

Object Relations and Identification

Freud introduced the concept of **object relations**, the psychological attachment to another person or object. He believed that the choice of a sexual partner in adulthood and the nature of that relationship depended on the quality of the child's object relationships during the early formative years.

The child's first love object is the mother, who is the source of nourishment and the provider of pleasure. Gradually, as the child separates from the mother, the nature of this initial attachment influences future relationships. The development of the child's capacity for relationships with others progresses from a state of narcissism to social relationships, first within the family and then within the larger community. Although the concept of object relations is fairly abstract, it can be understood in terms of a child who imitates their mother and then becomes like their mother in adulthood. This child incorporates their mother as a love object, identifies with her, and grows up to become like her. This process is especially important in understanding an abused child who, under certain circumstances, becomes an adult abuser.

Anxiety and Defense Mechanisms

For Freud, anxiety is the reaction to danger and is experienced as a specific state of physical unpleasantness. **Defense mechanisms** are coping styles that protect a person from unwanted anxiety. Although they are defined differently than in Freud day, defense mechanisms still play an explanatory role in contemporary psychiatric–mental health practice. Defense mechanisms are discussed in the chapter on Communication and the Therapeutic Relationship ([Chapter 10](#)).

Sexuality

The energy or psychic drive associated with the sexual instinct, or **libido**, literally translated from Latin to mean “pleasure” or “lust,” resides in the id. When sexual desire is controlled and not expressed, tension results and is transformed into anxiety (Freud, 1905). Freud believed that adult sexuality is an

end product of a complex process of development that begins in early childhood and involves a variety of body functions or areas (oral, anal, and genital zones) that correspond to stages of relationships, especially with parents.

Psychoanalysis

Freud developed **psychoanalysis**, a therapeutic process of accessing the unconscious conflicts that originate in childhood and then resolving the issues with a mature adult mind. As a system of psychotherapy, psychoanalysis attempts to reconstruct the personality by examining free associations (spontaneous, uncensored verbalizations of whatever comes to mind) and the interpretation of dreams. Therapeutic relationships had their beginnings within the psychoanalytic framework.

Transference and Countertransference

Transference is the displacement of thoughts, feelings, and behaviors originally associated with significant others from childhood onto a person in a current therapeutic relationship (Moore & Fine, 1990). For example, a woman's feelings toward her parents as a child may be directed toward the therapist. If a woman were unconsciously angry with her parents, she may feel unexplainable anger and hostility toward her therapist. In psychoanalysis, the therapist uses transference as a therapeutic tool to help the patient understand emotional problems and their origin.

Countertransference, on the other hand, is defined as the direction of all of the therapist's feelings and attitudes toward the patient. Countertransference becomes a problem when these feelings and perceptions are based on other interpersonal experiences. For example, a patient may remind a nurse of a beloved grandmother. Instead of therapeutically interacting with the patient from an objective perspective, the nurse feels an unexplained attachment to her and treats the patient as if she were the nurse's grandmother. The nurse misses important assessment and intervention data.

Neo-Freudian Models

Many of Freud's followers ultimately broke away, establishing their own forms of psychoanalysis. Freud did not receive criticism well. The rejection of some of his basic tenets often cost his friendship as well. Various psychoanalytic schools have adopted other names because their doctrines deviated from Freudian theory.

Adler's Foundation for Individual Psychology

Alfred Adler (1870–1937), a Viennese psychiatrist and founder of the school of individual psychology, was a student of Freud, who believed that the motivating force in human life is an intolerable sense of inferiority. Some people try to avoid these feelings by developing an unreasonable desire for power and dominance. This compensatory mechanism can get out of hand, and these individuals become self-centered and neurotic, overcompensate, and retreat from the real world and its problems.

Today, Adler's theories and principles are adapted and applied to both psychotherapy and education. Adlerian theory is based on principles of mutual respect, choice, responsibility, consequences, and belonging.

Jung Analytical Psychology

One of Freud's earliest students, Carl Gustav Jung (1875–1961), a Swiss psychoanalyst, created a model called analytical psychology. Jung believed in the existence of two basically different types of personalities: extroverted and introverted. Whereas extroverted people tend to be generally interested in other people and objects of the external world, introverted people are more interested in themselves and their internal environment. According to Jung, both extroverted and introverted tendencies exist in everyone, but the libido usually channels itself mainly in one direction or the other. He also developed the concept of *persona*—what a person appears to be to others in contrast to who they really are (Jung, 1966).

Horney Feminine Psychology

Karen Horney (1885–1952), a German American psychiatrist, challenged many of Freud's basic concepts and introduced principles of feminine psychology. Recognizing a male bias in psychoanalysis, Horney was the first to challenge the traditional psychoanalytic belief that women felt disadvantaged because of their genital organs. Freud believed that women felt inferior to men because their bodies were less completely equipped, a theory he described as "penis envy." Horney rejected this concept, as well as the oedipal complex, arguing that there are significant cultural reasons why women may strive to obtain qualities or privileges that are defined by a society as being masculine. For example, in Horney time, most women did not have access to a university education, the right to vote, or economic independence. She argued that women truly were at a disadvantage because of the paternalistic culture in which they lived (Horney, 1939).

Other Neo-Freudian Theories

Otto Rank: Birth Trauma

Otto Rank (1884–1939), an Austrian psychologist and psychotherapist, was also one of Freud's students. He attributed all neurotic disturbances to the primary trauma of birth. For Rank, human development is a progression from complete dependence on the mother and family to physical independence coupled with intellectual dependence on society and finally to complete intellectual and psychological emancipation. A person's will guides and organizes the integration of self.

Erich Fromm: Societal Needs

Erich Fromm (1900–1980), an American psychoanalyst, focused on the relationship of society and the individual. He argued that individual and societal needs are not separate and opposing forces; their relationship is determined by the historic background of the culture. Fromm also believed that the needs and desires of individuals are largely formed by their society. For Fromm, the

fundamental purpose of psychoanalysis and psychology is to bring harmony and understanding between the individual and society (Fromm-Reichmann, 1950).

Melanie Klein: Play Therapy

Melanie Klein (1882–1960), an Austrian psychoanalyst, devised play therapy techniques to demonstrate how a child's interaction with toys reveals earlier infantile fantasies and anxieties. She believed that complex, unconscious fantasies exist in children younger than 6 months of age. She is generally acknowledged as a pioneer in presenting an object relations viewpoint to the psychodynamic field, introducing the idea of early identification, a defense mechanism by which one patterns oneself after another person, such as a parent (Klein, 1963).

Harry Stack Sullivan: Interpersonal Forces

Interpersonal theories stress the importance of human relationships; instincts and drives are less important. Harry Stack Sullivan (1892–1949), an American psychiatrist, viewed **interpersonal relations** as a basis of human development and behavior. He believed that the health or sickness of one's personality is determined by the characteristic patterns in which one deals with other people. For example, one man is passive aggressive to everyone who contradicts him. This maladaptive behavior began when he was unable to express his disagreement to his parents. Health depends on managing the constantly changing physical, social, and interpersonal environment as well as past and current life experiences (Sullivan, 1953).

Humanistic Theories

Humanistic theories are based on the belief that all human beings have the potential for goodness. Humanist therapists focus on patients' ability to learn about and accept themselves. They do not investigate repressed memories. Through therapy, patients explore personal capabilities in order to develop self-worth. They learn to experience the world in a different way.

Rogers Client-Centered Therapy

Carl Rogers (1902–1987), an American psychologist, introduced client-centered therapy. **Empathy**, the capacity to assume the internal reference of the client in order to perceive the world in the same way as the client, is used in the therapeutic process (Rogers, 1980). The counselor is genuine but nondirect and also uses **unconditional positive regard**, a nonjudgmental caring for the client. In this therapy, the counselor's attitude and nonverbal communication are crucial. The therapist's emotional investment (i.e., true caring) in the client is essential in the therapeutic process (Rogers, 1980).

Gestalt Therapy

Another humanistic approach is Gestalt therapy, developed by Frederick S. (Fritz) Perls (1893–1970), a German-born former psychoanalyst who immigrated to the United States. Perls believed the root of human anxiety is frustration with inability to express natural biologic and psychological desires in modern civilization. The repression of these basic desires causes anxiety. In Gestalt therapy, these unmet needs are brought into awareness through individual and group exercises (Perls, 1969).

Abraham Maslow's Hierarchy of Needs

Abraham Maslow's (1921–1970) hierarchy of needs is fixture in social science and nursing (Maslow, 1970) ([Figure 7.1](#)). In nursing, Maslow model is used to prioritize care. Basic needs (food, shelter) should be met before higher-level needs (self-esteem) can be met.

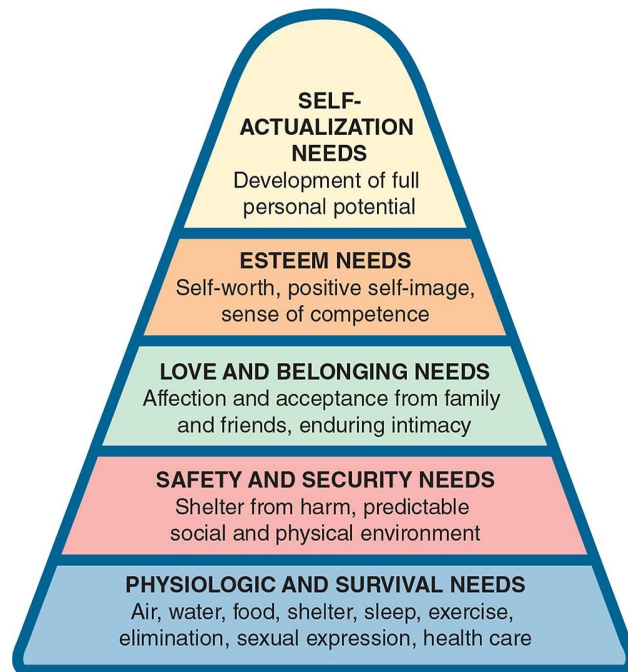

FIGURE 7.1 Maslow's hierarchy of needs.

Applicability of Psychodynamic Theories to Psychiatric–Mental Health Nursing

Several psychodynamic concepts are important in the practice of psychiatric–mental health nursing, such as interpersonal relationships, defense mechanisms, transference, countertransference, and internal objects. In particular, a therapeutic interpersonal relationship is a core of psychiatric–mental health nursing intervention (see [Chapter 11](#) for nursing interventions). Even though there is general consensus that most of these theories are useful, the nurse should continue to critically analyze them for utility and relevance. For example, Maslow theory may be useful when a person with mental illness is homeless and wants food and shelter. But, another person in a similar situation may reject food and shelter because self-esteem is associated with being free to reject the confines of an institution. In this case, self-esteem need is more important than food or shelter.

Recently, there is renewed interest in psychodynamic treatment for depression. Psychodynamic therapists have a strong emphasis on affect and emotional expression, examination of topics that the patient avoids, recurring patterns of

behaviors, feelings, experiences and relationships, the past and its influence on the present, interpersonal relationships, and exploration of wishes, dreams, and fantasies (Pitman & Knauss, 2020).

COGNITIVE-BEHAVIORAL THEORIES

Behavioral Theories

Behavioral theories attempt to explain how people learn and act. Behavioral theories never attempt to explain the cause of mental disorders; instead, they focus on normal human behavior. Research results are then applied to the clinical situation. Two areas of behavioral theories relevant to psychiatric–nursing practice are stimulus–response theories and reinforcement theories (Table 7.2).

Early Stimulus–Response Theories

Pavlovian Theory

One of the earliest behavioral theorists was Ivan P. Pavlov (1849–1936), who noticed that stomach secretions of dogs were stimulated by triggers other than food reaching the stomach. He found that the sight and smell of food triggered stomach secretions, and he became interested in this anticipatory secretion. Through his experiments, he was able to stimulate secretions with a variety of other laboratory nonphysiologic stimuli. Thus, a clear connection was made between thought processes and physiologic responses.

In Pavlov model, there is an unconditioned stimulus (not dependent on previous training) that elicits an unconditioned (i.e., specific) response. In his experiments, meat is the unconditioned stimulus, and salivation is the unconditioned response. Pavlov taught the dog to associate a bell (conditioned stimulus) with the meat (unconditioned stimulus) by repeatedly ringing the bell before presenting the meat. Eventually, the dog salivated when he heard the bell. This phenomenon is called **classical conditioning** (or Pavlovian conditioning) (Pavlov, 1927/1960).

John B. Watson and the Behaviorist Revolution

At about the same time Pavlov was working in Russia, **behaviorism**, a learning theory that only focuses on objectively observable behaviors and discounts any independent activities of the mind, was introduced in the United States by John B. Watson (1878–1958). He rejected the distinction between body and mind and emphasized the study of objective behavior (Watson & Rayner, 1920). He developed two principles: frequency and recency. The *principle of frequency* states that the more often a response is made to a stimulus, the more likely the response to that stimulus will be repeated. The *principle of recency* states that the closer in time a response is to a particular stimulus, the more likely the response will be repeated.

Reinforcement Theories

Edward L. Thorndike

A pioneer in experimental animal psychology, Edwin L. Thorndike (1874–1949) studied the problem-solving behavior of cats to determine whether animals solved 71problems by reasoning or instinct. He found that neither choice was completely correct; animals gradually learn the correct response by “stamping in” the stimulus–response connection. The major difference between Thorndike and behaviorists such as Watson was that Thorndike believed that reinforcement of positive behavior was important in learning. He was the first reinforcement theorist, and his view of learning became the dominant view in American learning theory (Thorndike, 1906).

TABLE 7.2 BEHAVIORAL THEORISTS			
Theorist	Overview	Major Concepts	Applicability
<i>Stimulus–Response</i>			
Edwin R. Guthrie (1886–	Continued with understanding	Recurrence of responses	Important in analyzing habitual

1959)	conditioning as being important in learning	tends to follow behavior a specific stimulus	
Ivan P. Pavlov(1849–1936)	Classical conditioning	Unconditioned stimuli Unconditioned response Conditioned stimuli	Important in understanding learning of automatic responses such as habitual behaviors
John B. Watson (1878–1958)	Introduced behaviorism Believed that learning was classical conditioning called <i>reflexes</i> Rejected distinction between mind and body	Principle of frequency Principle of recency	Focuses on the relationship between the mind and body
Reinforcement Theories			
B. F. Skinner(1904–1990)	Developed an understanding of the importance of reinforcement and differentiated types and schedules	Operant behavior Respondent behavior Continuous reinforcement Intermittent reinforcement	Important in behavior modification
Edward L. Thorndike(1874–1949)	Believed in the importance of effects that followed behavior	Reinforcement	Important in behavior modification programs

B. F. Skinner

One of the most influential behaviorists, B. F. Skinner (1904–1990) studied **operant behavior** or conditioning. In this type of learning, the focus is on the consequence of the behavioral response, not on a specific stimulus. If a behavior is reinforced or rewarded with success, praise, money, and so on, the behavior will probably be repeated. For example, if a child climbs on a chair, reaches the faucet, and is able to get a drink of water successfully, it is more likely that the child will repeat the behavior (Skinner, 1935). If a behavior does not have a

positive outcome, it is less likely that the behavior will be repeated. Nurses use this knowledge to create behavior management plans to reinforce healthy, positive behaviors.

Cognitive Theories

The initial behavioral studies focused on human actions without much attention to the internal thinking process. When complex behaviors could not be accounted for by strictly behavioral explanations, thought processes became new subjects for study. **Cognitive theory**, an outgrowth of different theoretic perspectives, including the behavioral and the psychodynamic, attempted to link internal thought processes with human behavior (Table 7.3).

Albert Bandura Social Cognitive Theory

Learning by watching others is the basis of Albert Bandura (b. 1925) social cognitive theory. He developed his ideas after being concerned about television violence contributing to aggression in children. He showed learning occurs by internalizing behaviors of others through a process of **modeling** called pervasive imitation, or one person trying to be like another. The model does not have to be a real person but could be a character in history or generalized to an ideal person (Bandura, 1977, 1986).

TABLE 7.3 COGNITIVE THEORISTS

Theorist	Overview	Major Concepts	Applicability
Aaron Beck(1921)	Conceptualized distorted cognitions as a basis for depression	Cognitions Beliefs	Important in cognitive therapy
Kurt Lewin (1890–1947)	Developed field theory, a system for understanding learning, motivation, personality, and social behavior	Life space Positive valences	Important in understanding motivation for changing

Edward Chace Tolman (1886–1959)	Introduced the concept of cognitions: believed that human beings act on beliefs and attitudes and strive toward goals	Negative valences Cognition	behavior Important in identifying person's beliefs
---------------------------------	---	--------------------------------	---

An important concept of Bandura's is **self-efficacy**, a person's sense of ability to deal effectively with the environment (Bandura, 1993). Efficacy beliefs influence how people feel, think, motivate themselves, and behave. The stronger the self-efficacy, the higher the goals people set for themselves and the firmer their commitment to them (Maine et al., 2017).

One of Bandura's recent contributions is showing that intentions and self-motivation play roles in determining behavior, significantly expanding the reinforcement model. He believes that the human mind is not only reactive to a stimulus but is also creative, proactive, and reflective (Bandura, 2001). Recent research supports Bandura ideas in accounting for goal achievement in entrepreneurship (Gielnik et al., 2020).

Aaron Beck: Thinking and Feeling

American psychiatrist Aaron T. Beck (b. 1921) of the University of Pennsylvania devoted his career to understanding the relationship between cognition and mental health. For Beck, **cognitions** are verbal or pictorial events in the stream of consciousness. He realized the importance of cognitions when treating people with depression. He found that depression improved when patients began viewing themselves and situations in a positive light.

He believes that people with depression have faulty information-processing systems that lead to biased cognitions. These faulty beliefs cause errors in judgment that become habitual errors in thinking. These individuals incorrectly interpret life situations, judge themselves too harshly, and jump to inaccurate negative conclusions. A person may truly believe that they have no friends, and therefore no one cares. On examination, the evidence for the beliefs is based on the fact that there has been no contact with anyone because of moving from one city to another. Thus, a distorted belief is the basis of the cognition. Beliefs are important because they are related to a person's mood. For example, negative beliefs of caregivers of family members with Alzheimer disorder are related to depression (see [Box 7.1](#)). Beck and his colleagues continue to develop cognitive

therapy, a successful approach for the treatment of depression (Beck, 2021).

BOX 7.1

Caregiver Beliefs and Depression

Crano, C., Lucidi, F., & Violani, C. (2017). The relationship between caregiving self-efficacy and depressive symptoms in family caregivers of patients with Alzheimer disease: a longitudinal study. International Psychogeriatrics, 29(7), 1095–1103.

THE QUESTION: Is there an association between caregiver's beliefs and depression?

METHODS: A three-wave design was used with initial assessment and follow-ups three months later and one year later. One hundred and seventy caregivers of patients with AD responded to measures of caregiver burden, caregiving self-efficacy (including control over upsetting beliefs about caregiving), and depressive symptoms.

FINDINGS: The caregiving burden at the time of the first assessment influenced the severity of depression one year later. The depressive symptoms were less severe when the caregivers believed that they had control over their upsetting thoughts about caregiving.

IMPLICATIONS FOR NURSING: Interventions that target caregivers' negative thoughts about the caregiving role may help them in coping with their situation.

Applicability of Cognitive-Behavioral Theories to Psychiatric–Mental Health Nursing

Basing interventions on behavioral theories is widespread in psychiatric nursing. For example, patient education interventions are usually derived from the behavioral theories. Teaching patients new coping skills for their symptoms of mental illnesses is another example. Changing an entrenched habit involves helping patients identify what motivates them and how these new lifestyle habits can become permanent. In psychiatric units, behavioral interventions include the privilege systems and token economies. Cognitive behavioral approaches are discussed throughout this text.

DEVELOPMENTAL THEORIES

Developmental theories explain normal human growth and development over time. Many developmental theories are presented in terms of stages based on the assumption that normal development proceeds longitudinally from the beginning to the ending stage.

Erik Erikson: Psychosocial Development

Freud and Sullivan both published treatises on stages of human development, but Erik Erikson (1902–1994) outlined the psychosocial developmental model that is most often used in nursing. Erikson model is an expansion of Freud psychosexual development theory. Whereas Freud model emphasizes intrapsychic experiences, Erikson model recognizes the role of the psychosocial environment. For example, parental divorce disrupts the family interaction pattern, and the financial and housing environment impact the development of the children.

Each of Erikson's eight stages is organized by age and developmental conflicts: basic trust versus mistrust, autonomy versus shame and doubt, initiative versus guilt, industry versus inferiority, identity versus role diffusion, intimacy versus isolation, generativity versus stagnation, and ego integrity versus despair. Successful resolution of a conflict or crisis leads to essential strength and virtues ([Table 7.4](#)). For example, a positive outcome of the trust versus mistrust crisis is the development of a basic sense of trust. If the crisis is unsuccessfully resolved, the infant moves into the next stage without a sense of trust. According to this model, a child who is mistrustful will have difficulty completing the next crisis successfully and, instead of developing a sense of autonomy, will more likely be full of shame and doubt (Erikson, 1963).

Identity and Adolescence

One of Erikson's major contributions is the recognition of the turbulence of adolescence and identity formation. When adolescence begins, childhood ways are given up, and bodily changes occur. An identity is formed. Trying to reconcile a personal view of self with society's perception can be overwhelming and lead to role confusion and alienation (Erikson, 1968).

Research Evidence for Erikson Models

Evidence is mixed that every person follows the eight stages of development as outlined by Erikson. In an early study, male college students who measured low on identity also scored low on intimacy ratings (Orlofsky et al., 1973). These results lend support to the idea that identity precedes intimacy. In another study, intimacy was found to begin developing early in adolescence before the development of identity (Ochse & Plug, 1986). Studying fathers with young children, Christiansen and Palkovitz (1998) found that *generativity* (defined as the need or drive to produce, create, or effect a change) was associated with a paternal identity, psychosocial identity, and psychosocial intimacy. In addition, fathers who had a religious identification also had higher generativity scores than did others.

TABLE 7.4 ERIKSON'S EIGHT AGES OF MAN

Approximate Chronologic Age	Developmental Conflict*	Long-Term Outcome of Successful Resolution
Infant	Basic trust vs. mistrust	Drive and hope
Toddler	Autonomy vs. shame and doubt	Self-control and willpower
Preschool-aged child	Initiative vs. guilt	Direction and purpose
School-aged child	Industry vs. inferiority	Method and competence
Adolescence	Identity vs. role diffusion	Devotion and fidelity
Young adult	Intimacy vs. isolation	Affiliation and love
Adulthood	Generativity vs. stagnation	Production and care
Maturity	Ego integrity vs. despair	Renunciation and wisdom

* Successful outcome is evidenced by the development of the characteristic listed first.

Adapted from Erikson, E. (1963). *Childhood and society* (pp. 273–274). W. W. Norton & Company.

A longitudinal study of 86 men beginning at age 21 years with reassessment 32 years later at age 53 years supports Erikson psychosocial eight-stage model (Westermeyer, 2004). In this study, 48 men (56%) achieved generativity at

follow-up. Successful young adults as predicted by Erikson model at midlife lived within a warm family environment; had an absence of troubled parental discipline; experienced a mentor relationship; and, most importantly, had favorable peer group relationships. The model is also used as a framework for psychodynamic psychotherapy (Knight, 2017).

Erikson model may apply differently to men and women. In one study, generativity is associated with well-being in both men and women, but in men, generativity is related to the urge for self-protection, self-assertion, self-expansion, and mastery. In women, the antecedents may be the desire for contact, connection, and union (Ackerman et al., 2000).

Studies show that generativity is significantly associated with successful marriage, work achievements, close friendships, altruistic behaviors, and overall mental health. Generativity is also associated with optimism and forgiveness in dealing with grandparenting problems within the family (Ehlman & Ligon, 2012; Pratt et al., 2008) and contemplating the meaning of life to older adults (Jonsén et al., 2015).

Jean Piaget: Learning in Children

One of the most influential people in child psychology is Jean Piaget (1896–1980), who contributed more than 40 books and 100 articles on child psychology alone. Piaget theory views intelligence as an adaptation to the environment. He proposes that cognitive growth is like embryologic growth: an organized structure becomes more and more differentiated over time. Piaget system explains how knowledge develops and changes (Table 7.5).

Each stage of cognitive development represents a particular structure with major characteristics. Piaget theory was developed through observation of his own children and therefore never received formal testing.

The major strength of his model is its recognition of the central role of cognition in development and the discovery of surprising features of young children's thinking. For example, children in middle childhood become capable of considering more than one aspect of an object or situation at a time. Their thinking becomes more complex. They can understand that the area of a rectangle is determined by the length *and* width. For psychiatric–mental health nurses, Piaget model provides a framework to recognize different levels of thinking in the assessment and intervention processes. For example, the

assessment of concrete thinking is typical of some people with schizophrenia who are unable to perform abstract thinking.

Carol Gilligan: Gender Differentiation in Moral Development

Carol Gilligan (b. 1936) argues that most development models are male centered and therefore inappropriate for girls and women. She challenges Erik Erikson (psychosocial development) and Kohlberg (moral) theories as being biased against women because they are based on primarily privileged, White men and boys. For Gilligan, attachment within relationships is the important factor for successful development. After comparing male and female personality development, she highlights differences (Gilligan, 2004). In developing identity, boys separate from their mothers, and girls attach. Girls probably learn to value relationships and become interdependent at an earlier age. They learn to value the ideal of care, begin to respond to human need, and want to take care of the world by sustaining attachments so no one is left alone. Her model of moral development, *Ethic of Care*, is divided into three stages beginning with *preconventional* or selfishness (what is best for me) to *conventional* or responsibility to others (self-sacrifice is goodness) to *postconventional* or do not hurt others or self (she is a person too) (Gilligan, 2011).

TABLE 7.5 **PIAGET PERIODS OF INTELLECTUAL DEVELOPMENT**

Age (years)	Period	Cognitive Developmental Characteristics	Description
Birth to 2	Sensorimotor	Divided into six stages, characterized by (1) inborn motor and sensory reflexes, (2) primary circular reaction and first habit, (3) secondary circular reaction, (4) use of familiar means to obtain ends, (5) tertiary circular	The infant understands the world in terms of overt, physical action on that world. The infant moves from simple reflexes through several steps to an organized set of schemes.

		reaction and discovery through active experimentation, and (6) insight and object permanence	Significant concepts are developed, including space, time, and causality. Above all, during this period, the child develops the scheme of the permanent object.
2–7	Preoperational	Deferred imitation; symbolic play, graphic imagery (drawing); mental imagery; and language egocentrism, rigidity of thought, semilogical reasoning, and limited social cognition	Child no longer only makes perceptual and motor adjustment to objects and events. Child can now use symbols (mental images, words, gestures) to represent these objects and events; uses these symbols in an increasingly organized and logical fashion.
7–11	Concrete operations	Conservation of quantity, weight, volume, length, and time based on reversibility by inversion or reciprocity; operations: class inclusion and seriation	Conservation is the understanding of what values remain the same. For example, if liquid is poured from a short, wide glass into a tall, narrow one, the preoperational child thinks that the quantity has changed. For the concrete operation child, the amount stays the same.
11 through the end of adolescence	Formal operations	Combination system whereby variables are isolated and all possible combinations are examined; hypothetical-deductive thinking	Mental operations are applied to objects and events. The child classifies, orders, and reverses them. Hypotheses can be generated from these

concrete operations.

Gilligan conclusion that female development depends on relationships has implications for everyone who provides care to women. Traditional models that advocate separation as the primary goal of human development immediately place women at a disadvantage. By negating the value and importance of attachments within relationships, the natural development of women is impaired. If Erikson model is applied to women, their failure to separate then becomes defined as a developmental failure (Gilligan, 1982).

Jean Baker Miller: A Sense of Connection

Jean Baker Miller (1927–2006) conceptualized female development within the context of experiences and relationships. Her landmark book, *Toward a New Psychology of Women* (1976/1986), led to the development of the relational-cultural theory, which identified a sense of connection as the central organizing feature of women's development. The goal of development is to increase a woman's ability to build and enlarge mutually enhancing relationships (Miller, 1994). **Connections** (mutually responsive and enhancing relationships) lead to mutual engagement (attention), empathy, and empowerment. In relationships in which everyone interacts beneficially, mutual psychological development can occur. **Disconnections** (lack of mutually responsive and enhancing relationships) occur when a child or adult expresses a feeling or explains an experience and does not receive any response from others. The most serious types of disconnection arise from the lack of response that occurs after abuse or attacks. The theory is currently evolving and serves as a model for psychotherapy and nursing practice on psychiatric units (Kress et al., 2018; Walker & Rosen, 2004).

75Applicability of Developmental Theories to Psychiatric–Mental Health Nursing

Developmental theories are used in understanding childhood and adolescent experiences and their manifestations as adult problems. When working with children, nurses can use developmental models to help gauge development and mood. However, because most of the models are based on the assumptions of the

linear progression of stages and have not been adequately tested, applicability has limitations. Most do not account for gender differences and diversity in lifestyles and cultures.

SOCIAL THEORIES

Numerous social theories underlie psychiatric–mental health nursing practice. [Chapter 3](#) presents some of the sociocultural issues and discusses various social groups. This section represents a sampling of important social theories that a nurse uses. This discussion is not exhaustive and should be viewed by the student as including a few of the important social theoretic perspectives.

Family Dynamics

Family dynamics are the patterned interpersonal and social interactions that occur within the family structure over the life of a family. Family dynamics models are based on systems theory in which the change of one part affects the total functioning of the system. The family is viewed organizationally as an open system in which one member's actions influence the functioning of the total system. Family theories are especially useful to nurses who are assessing family dynamics and planning interventions. Family systems models are used to help nurses form collaborative relationships with patients and families dealing with health problems. Generalist psychiatric–mental health nurses will not be engaged in family therapy. However, they will be caring for individuals and families. Understanding family dynamics is important in every nurse's practice.

Formal and Informal Social Support

Assisting patients in the recovery process means helping patients identify supportive family and community systems. **Formal support systems** are large organizations, such as hospitals and nursing homes that provide care to individuals. **Informal support systems** are family, friends, and neighbors. Individuals with strong informal support networks actually live longer than those

without this type of support. Adolescents who are survivors of sexual assault are more likely to seek support from informal support systems than formal supports (Fehler-Cabral & Campbell, 2013). In addition, classic studies showed that those without informal support have significantly higher mortality rates when the causes of death are accidents (e.g., smoking in bed) or suicides (Litwak, 1985).

An important concept is **social distance**, the degree to which the values of the formal organization and primary group members differ. In the United States, the most closely located, accessible, and available family member is expected to provide the care to a family member. Spouses are the first choice, then children, other family members, friends, and finally formal support. On the other, care-related stress can result in the informal caregiver changing the balance by placing a family member in an institution (Friedemann et al., 2014).

Formal and informal support systems are balanced when they are at a midpoint of social distance, that is, close enough to communicate but not so close to destroy each other—neither enmeshment nor isolation (Litwak et al., 1990; Messeri et al., 1993). Conflicts arise when the relationship becomes unbalanced. For example, if the primary group and the formal care system begin performing similar caregiving services, there may be disagreements. Balance is reestablished when the formal system increases the social distance by developing relationships and providing support to the caregiver and reducing contact with the patient. Thus, a balance is maintained between the two systems. In another instance, when a patient relies only on the health care provider for care and support (e.g., calls the nurse every day, visits the physician weekly, refuses any help from family), balance can be reestablished by linking the patient to an informal support system for help with some of the caregiving tasks.

By applying frameworks of formal and informal support systems to their patients, psychiatric nurses can understand the complex social forces that patient's with mental disorders and their caregivers experience (McPherson et al., 2013) (**Box 7.2**). Nurses can help adjust the social distance between the formal and informal systems by identifying communication barriers and helping the two groups work together. For example, a patient misses an appointment because of a lack of transportation. The case manager helps the patient communicate the problem to the system to obtain another appointment. Informal caregivers are valued by the case manager, who recognizes the important services performed by family and friends. Thus, linkages between mental health providers (formal support) and the consumer network (informal support) are reinforced.

Role Theories

A role is a person's social position and function within an environment. Anthropologic theories explain members' roles that relate to a specific society. For example, the 76universal roles of healer may be assumed by a nurse in one culture and a spiritual leader in another. Societal expectations, social status, and rights are attached to these roles. Psychological theories, which are concerned about roles from a different perspective, focus on the relationship of an individual's role: the self. The responsibilities of a parent are often in conflict with the personal needs for time alone. All of the neo-Freudian and humanist models that have been discussed focus on reciprocal social relationships or interactions that determine how the mind develops.

BOX 7.2

Formal and Informal Support to Caregivers

Verbakel, E., Metzelthin, S.F., & Kempen, G.I.J.M. (2018). Caregiving to older adults: Determinants of informal caregivers' subjective well-being and formal and informal support as alleviating conditions. *The Journals of Gerontology. Series B, Psychological Sciences*, 73(6), 1099–1111.
<https://doi.org/10.1093/geronb/gbw047>

THE QUESTION: Are there relationships among informal caregivers' subjective well-being and primary stressors, hours of informal caregiving, and burden? Does formal (professional home care) and informal support (from other caregivers, family, and friends) alleviate well-being losses due to providing informal care?

METHODS: Data from 4,717 dyads of informal caregivers and their older care recipients were analyzed.

FINDINGS: Caregivers' subjective well-being was directly related to the burden, hours of informal caregiving, and problem behavior of the care recipients. Formal and informal support reduced the impact of the primary stressors and caregiving hours. Reduction of formal/professional care may increase the negative well-being of caregivers.

IMPLICATIONS FOR NURSING: Formal and informal support to caregivers can promote well-being for caregivers.

Role theories emphasize the importance of social interaction in either the individual's choice of a particular role or society's recognition of it. Psychiatric–mental health nursing uses role concepts in understanding group interaction and

the role of the patient in the family and community. In addition, milieu therapy approaches discussed in later chapters are based on the patient's assumption of a role within the psychiatric environment.

Sociocultural Perspectives

Margaret Mead: Culture and Gender

American anthropologist Margaret Mead (1901–1978) is widely known for her studies of primitive societies and her contributions to social anthropology. She conducted studies in New Guinea, Samoa, and Bali and devoted much of her studies to the patterns of child-rearing in various cultures. She was particularly interested in the cultural influences determining male and female behavior (Mead, 1970). Influenced by Carl Jung and Erik Erikson, she had a vision of unity and diversity of the psychosocial development of a single human species (Sullivan, 2004). Although her research is often criticized as not having scientific rigor and being filled with misinterpretations, it is accepted as a classic in the field of anthropology (Sullivan, 2004). She established the importance of culture in determining human behavior.

BOX 7.3

Cultural Knowledge of Mental Health Beliefs and Practices

Wolf, K.M. (2016). Somali immigrant perceptions of mental health and illness: An ethnonursing study. *Journal of Transcultural Nursing*, 27(4), 349–358.

QUESTION: What are the mental health meanings, beliefs, and practices from the perspective of immigrant Somalis?

METHODS: Qualitative ethnonursing research methods were used. Thirty informants (9 key and 21 general) were interviewed in community settings.

FINDINGS: Analysis of the interviews revealed 21 categories and 9 patterns. Two main themes emerged: Religion significantly influences their mental health, and religious beliefs and practices influence their health care choices.

IMPLICATIONS FOR NURSING: Culturally congruent care will improve care for Somali immigrants.

Madeleine Leininger: Transcultural Health Care

Concern about the impact of culture on the treatment of children with psychiatric and emotional problems led Madeleine Leininger (1924–2012) to develop a new field, transcultural nursing, directed toward holistic, congruent, and beneficent care. Leininger developed the *Theory of Culture Care Diversity and Universality*, which explains diverse and universal dimensions of human caring (Figure 7.2). Nursing care in one culture is different from another because definitions of health, illness, and care are culturally defined (Leininger & McFarland, 2006). The goal of Leininger theory is to discover culturally based care (Leininger, 2007). Leininger model continues to be used today as a framework for understanding mental health beliefs of various ethnic groups (Wolf et al., 2016), Alzheimer disease (Barbosa et al., 2020), and violence against women (Broch et al., 2017) (see Box 7.3).

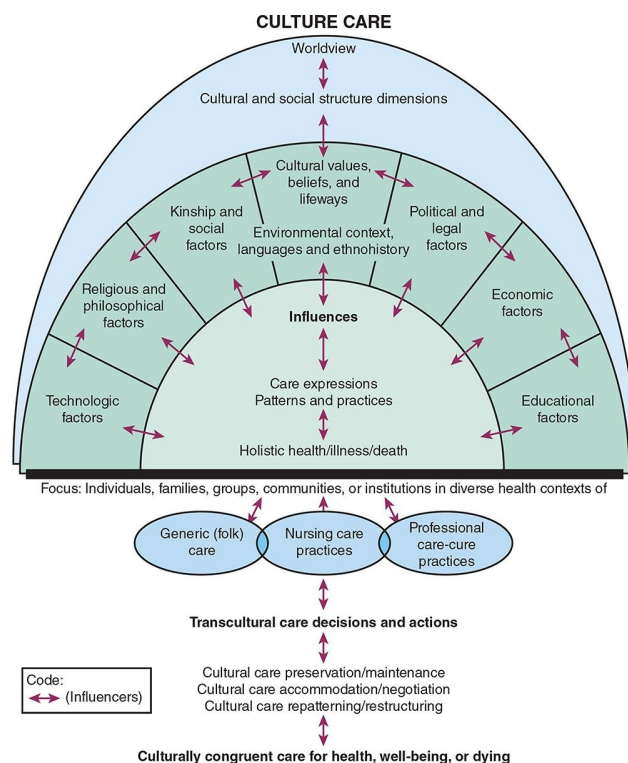

FIGURE 7.2 Leininger sunrise model to depict theory of cultural care diversity and universality.

Applicability of Social Theories to Psychiatric–Mental Health Nursing

The use of social and sociocultural theories is especially important for psychiatric–mental health nurses. In any individual or family assessment, the sociocultural aspect is integral to mental health. It would be impossible to complete an adequate assessment without considering the role of the individual within the family and society. Interventions are based on the understanding and significance of family and cultural norms. It would be impossible to interact with the family in a meaningful way without an understanding of the family’s cultural values. In the inpatient setting, the nurse is responsible for designing the social environment of the unit as well as ensuring that the patient is safe from harm. To accomplish this complex task, an understanding of the unit as a small social community helps the nurse use the environment in patient treatment (see [Chapter 11](#)). In addition, many group interventions are based on sociocultural theories (see [Chapter 14](#)).

NURSING THEORIES

Nursing theories are useful to psychiatric–mental health nursing in conceptualizing the individual, family, or community and in planning nursing interventions (see [Chapter 11](#)). The use of a specific theory depends on the patient situation. For example, in people with schizophrenia who have problems related to maintaining self-care, Dorothea Orem theory of self-care is useful. By contrast, Hildegard Peplau theories are appropriate when a nurse is developing a relationship with a patient. Because of the wide range of possible problems requiring different approaches, familiarity with several nursing theories is essential.

Interpersonal Relations Models

Hildegard Peplau: The Power of Empathy

Hildegard Peplau (1909–1999) introduced the first systematic theoretic framework for psychiatric nursing and focused on the nurse–patient relationship in her book *Inter-personal Relations in Nursing* in 1952 (Peplau, 1952). She led psychiatric–mental health nursing out of the confinement of custodial care into a theory-driven professional practice. One of her major contributions was the

introduction of the nurse–patient relationship (see [Chapter 10](#)).

Peplau believed in the importance of the environment, defined as external factors considered essential to human development (Peplau, 1992): cultural forces, presence of adults, secure economic status of the family, and a healthy prenatal environment. Peplau emphasized the importance of empathic linkage.

KEYCONCEPT Empathic linkage is the ability to feel in oneself the feelings experienced by another person.

The interpersonal transmission of anxiety or panic is the most common empathic linkage. According to Peplau, other feelings, such as anger, disgust, and envy, can also be communicated nonverbally by way of empathic transmission to others. Although the process is not yet understood, she explains that empathic communication occurs. She believes that if nurses pay attention to what they feel during a relationship with a patient, they can gain invaluable observations of feelings a patient is experiencing and has not yet noticed or talked about.

Anxiety is a key concept for Peplau, who contends that professional practice is unsafe if this concept is not understood.

KEYCONCEPT Anxiety, according to Peplau, is an energy that arises when expectations that are present are not met.

If anxiety is not recognized, it continues to rise and escalates toward panic. There are various levels of anxiety, each having its observable behavioral cues ([Box 7.4](#)). These cues are sometimes called *defensive*, but Peplau argues that they are often “relief behaviors.” For example, some people may relieve their anxiety by yelling and swearing; others seek relief by withdrawing. In both instances, anxiety was generated by an unmet security need.

BOX 7.4

Levels of Anxiety

Mild: awareness heightens
Moderate: awareness narrows
Severe: focused narrow awareness
Panic: unable to function

NCLEXNOTE Peplau model of anxiety continues to be an important concept in psychiatric nursing. Severe anxiety interferes with learning. Mild anxiety is useful for learning.

The **self-system** is another important concept in Peplau model. Drawing from Sullivan, Peplau defined the self as an “anti-anxiety system” and a product of socialization. The self proceeds through personal development that is always open to revision but tends toward stability. For example, in parent–child relationships, patterns of approval, disapproval, and indifference are used by children to define themselves. If the verbal and nonverbal messages have been derogatory, children incorporate these messages and also view themselves negatively.

The concept of need is important to Peplau model. Needs are primarily of biologic origin but need to be met within a sociocultural environment. When a biologic need is present, it gives rise to tension that is reduced and relieved by behaviors meeting that need. According to Peplau, nurses should recognize and support the patients’ patterns and style of meeting their health care needs.

Ida Jean Orlando

In 1954, Ida Jean Orlando (1926–2007) studied the factors that enhanced or impeded the integration of mental health principles in the basic nursing curriculum. From this study, she published *The Dynamic Nurse–Patient Relationship* to offer nursing students a theory of effective nursing practice. She studied nursing care of patients on medical–surgical units, not people with psychiatric problems in mental hospitals. Orlando identified three areas of nursing concern: the nurse–patient relationship, the nurse’s professional role, and the identity and development of knowledge that is distinctly nursing (Orlando, 1961). A nursing situation involves the behavior of the patient, the reaction of the nurse, and anything that does not relieve the distress of the patient. Patient distress is related to the inability of the individual to meet or communicate their own needs (Orlando, 1961, 1972).

Orlando helped nurses focus on the whole patient rather than on the disease or institutional demands. Her ideas continue to be useful today, and current research supports her model (Olson & Hanchett, 1997). A small nursing study investigated whether Orlando nursing theory–based practice had a measurable impact on patients’ immediate distress when compared with nonspecified

nursing interventions. Orlando approach consisted of the nurse validating the patient's distress before taking any action to reduce it. Patients being cared for by the Orlando group experienced significantly less stress than those receiving traditional nursing care (Potter & Bockenbauer, 2000). Orlando model has been used in many settings, including fall prevention in a hospital (Abraham, 2011). Orlando theory is also proposed as a model for teaching communication in nursing programs (Gaudet & Howett, 2018).

Existential and Humanistic Theoretical Perspectives

Rosemarie Rizzo Parse

The *Humanbecoming Theory* views humans as indivisible, unpredictable, ever-changing coauthors and experts about their lives (Parse, 1998, 2007). Three major themes underlie this theory: meaning (personal meaning to the situation), rhythmicity (the paradoxical patterning of the human–universe mutual processes—the ups and downs of life), and transcendence (power and originating of transforming) (Parse, 1996, 1998, 2008). The postulates involved in living a human life are *illuminating* (unbound knowing extended to infinity), *paradox* (intricate rhythm expressed as a pattern preference), *freedom* (liberation), and *mystery* (unexplainable) (Parse, 2007).

The theory was expanded to address the ethos of humanbecoming with the core knowings of living quality. The four tenets of humanbecoming are *reverence* (solemn regard for humanuniverse presence), *awe* (beholding the unexplainable of humanuniverse existence), *betrayal* (the violation of humanuniverse trust), and *shame* (humiliation with dishonoring humanuniverse worth) (Parse, 2018).

As one of the more abstract nursing theories, *humanbecoming* can be used in understanding patients' life experiences and connecting psychologically with a patient. This theory has been widely studied in nursing and adds qualitative dimension to understanding the patient's human experience. For example, one of the studies explores freedom from a humanbecoming perspective (Bunkers, 2020). Parse theory is recommended as an alternative to the medical approach for a grieving family who has experienced a pregnancy loss, still birth, or neonatal death. The theory of humanbecoming focuses of quality of life as experienced and the meaning of the experience as perceived by the parents

(Wilson et al., 2016).

Jean Watson

The theory of transpersonal caring was initiated by Jean Watson (b. 1940). Watson believes that caring is the foundation of nursing and recommends that specific theories of caring be developed in relation to specific human conditions and health and illness experiences (Watson, 2005). Her conceptualizations transcend conventional views of illness and focus on the meaning of health and quality of life (Watson, 2007). There are three foundational concepts of her theory:

- Transpersonal Caring–Healing Relations: a relational process related to philosophic, moral, and spiritual foundation.
- Ten Caritas Process: the original 10 Carative Factors have evolved into the 10 Caritas Processes ([Box 7.5](#)).
- Caritas Field: a field of consciousness created when the nurse focuses on love and caring as their way of being and consciously manifests a healing presence with others.

BOX 7.5

Nursing: Human Science and Human Care Assumptions, and Factors in Care

Assumptions

1. Caring can be effectively demonstrated and practiced only interpersonally.
2. Caring consists of factors that result in the satisfaction of certain human needs.
3. Effective caring promotes health and individual or family growth.
4. Caring responses accept a person not only as they are now but also as what they may become.
5. A caring environment offers the development of potential while allowing the person to choose the best action for themselves at a given point in time.
6. Caring is more “healthogenic” than is curing. It integrates biophysical knowledge with knowledge of human behavior to generate or promote health and provide ministrations to those who are ill. A science of caring is complementary to the science of curing.
7. The practice of caring is central to nursing.

10 Caritas Processes™

1. Embrace altruistic values and practice loving kindness with self and others.
2. Instill faith, hope, and honor in others.
3. Be sensitive to self and others by nurturing individual beliefs and practices.
4. Develop helping–trusting–caring relationships.

5. Promote and accept positive and negative feelings as you authentically listen to another's story.
6. Use creative scientific problem-solving methods for caring decision-making.
7. Share teaching and learning that address the individual needs and comprehension styles.
8. Create a healing environment for the physical and spiritual self that respects human dignity.
9. Assist with basic physical, emotional, and spiritual human needs.
10. Be open to mystery and allow miracles to enter.

Reprinted with permission from Jean Watson and Watson Caring Science Institute, International Caritas Consortium. (2010). Dr. Jean Watson's Human Caring Theory: Ten Caritas Processes®.

<http://www.watsoncaringscience.org/about-us/caring-science-definitions-processes-theory/>

Watson theory is especially applicable to the care of those who seek help for mental illness. This model emphasizes the importance of sensitivity to self and others; the development of helping and trusting relations; the promotion of interpersonal teaching and learning; and provision for a supportive, protective, and corrective mental, physical, sociocultural, and spiritual environment. Watson caring science-based interventions have been shown to decrease patient's emotional strains, increase patients' self-management confidence and emotional well-being, increase nurses' job satisfaction and engagement, and improve nursing students' confidence in the clinical performance and the awareness of caring behaviors (Holly et al., 2019).

Systems Models

Imogene M. King

The theory of goal attainment developed by Imogene King (1923–2007) is based on a systems model that includes three interacting systems: personal, interpersonal, and social. In this model, human beings interact with the environment, and the individual's perceptions influence reactions and interactions (Figure 7.3). Nursing involves caring for the human being, with the goal of health defined as adjusting to the stressors in both internal and external environments (King, 2007). She defines nursing as a “process of human interactions between nurse and patient whereby each perceives the other and the situation; and through communication, they set goals, explore means, and agree on means to achieve goals” (King, 1981, p. 144). This model focuses on the process that occurs between a nurse and a patient. The process is initiated to help the patient cope with a health problem that compromises their ability to maintain social roles, functions, and activities of daily living (King, 1992).

FIGURE 7.3 Imogene King's conceptual framework for nursing: dynamic interacting systems.

In this model, the person is goal oriented and purposeful, reacting to stressors, and is viewed as an open system interacting with the environment. The variables in nursing situations are as follows:

- Geographic place of the transacting system, such as the hospital
- Perceptions of the nurse and patient
- Communications of the nurse and patient
- Expectations of the nurse and patient
- Mutual goals of the nurse and patient
- The nurse and patient as a system of interdependent roles in a nursing situation (King, 1981, p. 88)

The quality of nurse–patient interactions may have positive or negative influences on the promotion of health in any nursing situation. It is within this interpersonal system of nurse and patient that the healing process is performed. Interaction is depicted in which the outcome is a **transaction**, defined as the transfer of value between two or more people. This behavior is unique, based on experience, and is goal directed.

King's work reflects her understanding of the systematic process of theory development. Her model continues to be developed and applied in national and international settings, including psychiatric–mental health care (Shanta & Connolly, 2013). The model also serves as a basis for a recent nursing theory related to work team/group empowerment. The theory is applied to improve

nurses' empowerment within health care organizations (Friend & Sieloff, 2018).

Betty Neuman

Betty Neuman (b. 1924) uses a systems approach as a model of nursing care. Neuman wants to extend care beyond an illness model, incorporating concepts of problem finding and prevention and the newer behavioral science concepts and environmental approaches to wellness. Neuman developed her framework in the late 1960s as chairwoman of the University of California at Los Angeles graduate nursing program. The key components of the model are a client system (physiological, psychological, sociocultural, developmental, spiritual) interacting with the environment. The wholistic model can be applied to prevention and treatment. Expansion of the model is an area of interest because of the need to define and describe her concept of social issues (Aronowitz & Fawcett, 2016).

Neuman was one of the first psychiatric nurses to include the concept of stressors in understanding nursing care. The Neuman systems model is applied to practice and educational settings, including community health, family therapy, renal nursing, perinatal nursing, and mental health nursing of older adults (Beckman et al., 2012; Neuman & Fawcett, 2011). This model has been applied to the practice and educational setting, including international programs (Greco et al., 2016; Olowokere & Okanlawon, 2015; Vanaki & Rafiei, 2020).

Dorothea Orem

Self-care is the focus of the general theory of nursing initiated by Dorothea Orem (1914–2007) in the early 1960s. The Self-Care Deficit Nursing Theory consists of three separate parts: a theory of self-care, theory of self-care deficit, and theory of nursing systems (Biggs, 2008; Orem, 2001; Orem & Taylor, 2011). The theory of self-care defines the term as activities performed independently by an individual to promote and maintain personal well-being throughout life. The central focus of Orem theory is the self-care deficit theory, which describes how people can be helped by nursing. Nurses can help meet self-care requisites through five approaches: acting or doing for, guiding, teaching, supporting, and providing an environment to promote the patient's ability to meet current or

future demands. The nursing systems theory refers to a series of actions a nurse takes to meet the patient's self-care requisites. This system varies from the patient being totally dependent on the nurse for care to needing only some education and support.

Orem model is used in psychiatric–mental health nursing because of its emphasis on promoting independence of the individual and on self-care activities (Burdette, 2012; Seed & Torkelson, 2012; Wazni & Gifford, 2017). Although many psychiatric disorders have an underlying problem, such as motivation, these problems are generally manifested as difficulties conducting ordinary self-care activities (e.g., personal hygiene) or developing independent thinking skills.

Other Nursing Theories

Other nursing models are applied in psychiatric settings. Martha Rogers model of unitary human beings and Calista Roy adaptation model have been the basis of many psychiatric nursing approaches.

SUMMARY OF KEY POINTS

- The traditional psychodynamic framework helped form the basis of early nursing interpersonal interventions, including the development of therapeutic relationships and the use of such concepts as transference, countertransference, empathy, and object relations.
- The behavioral theories are often used in strategies that help patients change behavior and thinking.
- Sociocultural theories remain important in understanding and interacting with patients as members of families and cultures.
- Nursing theories form the conceptual basis for nursing practice and are useful in a variety of psychiatric–mental health settings.

CRITICAL THINKING CHALLENGES

1. Discuss the similarities and differences among Freud ideas and those of the neo-Freudians, including Jung, Adler, Horney, and Sullivan.
2. Compare and contrast the basic ideas of psychodynamic and behavioral theories.
3. Compare and differentiate classic conditioning from operant conditioning.
4. Define the following terms and discuss their applicability to psychiatric–mental health nursing: classical conditioning, operant conditioning, positive reinforcement, and negative reinforcement.
5. List the major developmental theorists and their main ideas.
6. Discuss the cognitive therapy approaches to mental disorders and how they can be used in psychiatric–mental health nursing practice.
7. Define formal and informal support systems. How does the concept of social distance relate to these two systems?
8. Compare and contrast the basic ideas of the nursing theorists.

Randy Adams

Part 1 (Cognitive Behavioral Social Theories)

Randy Adams, a 28-year-old veteran exposed to bomb blasts during combat in the Middle East,

has symptoms of posttraumatic stress disorder and neurocognitive problems. How can cognitive-behavioral and social theories be applied to his condition? How does an understanding of psychosocial theories assist the nurse in selecting suitable interventions to promote psychological and social functioning?

Movie Viewing Guides

Freud: 1962. This film depicts Sigmund Freud as a young physician, focusing on his early psychiatric theories and treatments. His struggles for acceptance of his ideas among the Viennese medical community are depicted. This fascinating film is well done and gives an interesting overview of the impact of psychoanalysis.

VIEWING POINTS: Watch for the impact on political thinking during the gradual acceptance of Freud ideas. Discuss the “dream sequence” and its impact on the development of psychoanalysis as a therapeutic technique.

An Angel at My Table: 1990, New Zealand. This three-part television miniseries tells the story of Janet Frame, New Zealand’s premiere novelist and poet. Based on her autobiography, the film portrays Frame as a shy, awkward child who experiences a family tragedy that alienates her socially. She studies in England to

be a teacher, but her shyness and social ineptness cause extreme anxiety. Seeking mental health care, she receives a misdiagnosis of schizophrenia and spends 8 years in a mental institution. She barely escapes a lobotomy when she is notified of a literary award. She then begins to develop friendships and a new life.

VIEWING POINTS: Observe Janet Frame’s childhood development. Does she “fit” any of the models that are discussed in this chapter? Consider her life in light of Gilligan and Miller theories that it is important for women to have a sense of connection.

Biologic Foundations of Psychiatric Nursing

Mary Ann Boyd

KEYCONCEPTS

- neuroplasticity
- neurotransmitters

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Describe the association between biologic functioning and symptoms of psychiatric disorders.
2. Locate brain structures primarily involved in psychiatric disorders and describe the primary functions of these structures.
3. Describe basic mechanisms of neuronal transmission.
4. Identify the location and function of neurotransmitters significant to hypotheses regarding major mental disorders.
5. Discuss the role of genetics in the development of psychiatric disorders.
6. Discuss the basic utilization of new knowledge gained from fields of study, including psychoneuroimmunology and chronobiology.

Key Terms

- Acetylcholine
- Amino acids
- Autonomic nervous system
- Basal ganglia
- Biogenic amines
- Biologic markers
- Brain stem
- Cerebellum
- Chronobiology
- Circadian cycle
- Cortex
- Dopamine
- Enteric nervous system
- Extrapyrarnidal motor system
- Frontal, parietal, temporal, and occipital lobes
- Functional imaging
- Gut–brain axis
- Gut microbiota
- GABA
- Genetic susceptibility
- Glutamate
- Hippocampus
- Histamine
- Hypothalamus–pituitary–thyroid axis

- Limbic system
 - Locus coeruleus
 - Neurocircuitry
 - Neurohormones
 - Neurons
 - Neuromodulators
 - Neuropeptides
 - Norepinephrine
 - Phenotype
 - Pineal body
 - Population genetics
 - Proband
 - Psychoneuroimmunology
 - Receptor
 - Serotonin
 - Structural imaging
 - Synaptic cleft
 - Working memory
 - Zeitgebers
-

INTRODUCTION

All behavior recognized as human results from actions that originate in the brain and its amazing interconnection of neural networks. Modern research has increased understanding of how the complex circuitry of the brain interacts with the external environment, memories, and experiences. Through the spinal column and peripheral nerves, along with other systems, such as the endocrine and immune systems, the brain constantly receives and processes information. As the brain shifts and sorts through the amazing amount of information it processes every hour, it decides on actions and initiates behaviors, allowing each person to act in entirely unique and very human ways.

85Mental disorders cannot be traced to specific physiologic problems but rather are complex syndromes consisting of symptoms that more or less cluster together. Therefore, it is important for the nurse to understand basic nervous system functioning, as well as some of the research that is exploring the biologic

basis of mental disorders.

This chapter reviews the basic information necessary for understanding neuroscience as it relates to the role of the psychiatric–mental health nurse. It reviews basic central nervous system (CNS) structures and functions, the peripheral nervous system (PNS), general functions of the major neurotransmitters and **receptors**, basic principles of neurotransmission, genetic models, circadian rhythms, and biologic tests. The chapter assumes that the reader has a basic knowledge of human biology, anatomy, and pathophysiology. It is not intended as a full presentation of neuroanatomy and physiology but rather as an overview of the structures and functions most critical to understanding the role of the psychiatric–mental health nurse. Psychiatric–mental health nurses must be able to make the connection between (1) patients' psychiatric symptoms, (2) the probable alterations in brain functioning linked to those symptoms, and (3) the rationale for treatment and care practices.

NEUROANATOMY OF THE CENTRAL NERVOUS SYSTEM

Although this section discusses functioning areas of the brain separately, each area is intricately connected with the others, and each functions interactively. The CNS contains the brain, **brain stem**, and spinal cord, and the PNS consists of the **neurons** that connect the CNS to the muscles, organs, and other systems in the periphery of the body. Whatever affects the CNS may also affect the PNS and vice versa.

FIGURE 8.1 Lateral and medial surfaces of the brain. Left: The left lateral surface of the brain. Right: The medial surface of the right half of a sagittally

hemisected brain. (Reprinted with permission from Bear, M. F., Connors, B. W., & Paradiso, M. A. [2016]. Neuroscience: Exploring the brain [4th ed.]. Wolters Kluwer.)

Cerebrum

The largest region of the human brain, the cerebrum fills the entire upper portion of the cranium. The **cortex**, or outermost surface of the cerebrum, makes up about 80% of the human brain. The cortex is four to six cellular layers thick, and each layer is composed of cell bodies mixed with capillary blood vessels. This mixture makes the cortex gray brown (thus the term *gray matter*). The cortex consists of numerous bumps and grooves in a fully developed adult brain, as shown in [Figure 8.1](#). This “wrinkling” allows for a large amount of surface area to be confined in the limited space of the skull. The increased surface area allows for more potential connections among cells within the cortex. The grooves are called *fissures* if they extend deep into the brain and *sulci* if they are shallower. The bumps or convolutions are called *gyri*. Together they provide many of the landmarks for the subdivisions of the cortex. The longest and deepest groove, the longitudinal fissure, separates the cerebrum into left and right hemispheres. Although these two divisions are nearly symmetric, there is some variation in the location and size of the sulci and gyri in each hemisphere. Substantial variation in these convolutions is found in the cortex of different individuals.

86Left and Right Hemispheres

The cerebrum can be roughly divided into two halves, or hemispheres. The left hemisphere is dominant in about 95% of people, but about 5% of individuals have mixed dominance. Each hemisphere controls functioning mainly on the opposite side of the body. Aside from controlling activities on the left side of the body, the right hemisphere also provides input into receptive nonverbal communication, spatial orientation and recognition, intonation of speech and aspects of music, facial recognition and facial expression of emotion, and nonverbal learning and memory. In general, the left hemisphere is more involved with verbal language function, including areas for both receptive and expressive

speech control, and provides strong contributions to temporal order and sequencing, numeric symbols, and verbal learning and memory.

The two hemispheres are connected by the corpus callosum, a bundle of neuronal tissue that allows information to be exchanged quickly between the right and left hemispheres. An intact corpus callosum is required for the hemispheres to function in a smooth and coordinated manner.

Lobes of the Brain

The lateral surface of each hemisphere is further divided into four lobes: **the frontal, parietal, temporal, and occipital lobes** (see Fig. 8.1). The lobes work in coordinated ways, but each is responsible for specific functions. An understanding of these unique functions is helpful in understanding how damage to these areas produces the symptoms of mental illness and how medications that affect the functioning of these lobes can produce certain effects.

Frontal Lobes

The right and left frontal lobes make up about one fourth of the entire cerebral cortex and are proportionately larger in humans than in any other mammal. The precentral gyrus, the gyrus immediately anterior to the central sulcus, contains the primary motor area, or homunculi. Damage to this gyrus or to the anterior neighboring gyri causes spastic paralysis in the opposite side of the body. The frontal lobe also contains Broca area, which controls the motor function of speech. Damage to Broca area produces expressive aphasia or difficulty with the motor movements required for speech. The frontal lobes are also thought to contain the highest or most complex aspects of cortical functioning, which collectively make up a large part of what we call personality. **Working memory** is an important aspect of frontal lobe function, including the ability to plan and initiate activity with future goals in mind. Insight, judgment, reasoning, concept formation, problem-solving skills, abstraction, and self-evaluation are all abilities that are modulated and affected by the actions of the frontal lobes. These skills are often referred to as *executive functions* because they modulate more primitive impulses through numerous connections to other areas of the cerebrum.

When normal frontal lobe functioning is altered, executive functioning is

decreased, and modulation of impulses can be lost, leading to changes in mood and personality. The importance of the frontal lobe and its role in the development of symptoms common to psychiatric disorders are emphasized in later chapters that discuss disorders such as schizophrenia, attention-deficit hyperactivity disorder, and dementia. [Box 8.1](#) describes how altered frontal lobe function can affect mood and personality.

BOX 8.1

Frontal Lobe Syndrome

In the 1860s, Phineas Gage became a famous example of frontal lobe dysfunction. Mr. Gage was a New England railroad worker who had a thick iron-tamping rod propelled through his frontal lobes by an explosion. He survived but suffered significant changes in his personality. Mr. Gage, who had previously been a capable and calm supervisor, began to show impatience, labile mood, disrespect for others, and frequent use of profanity after his injury (Harlow, 1868). Similar conditions are often called *frontal lobe syndrome*. Symptoms vary widely from individual to individual. In general, after damage to the dorsolateral (upper and outer) areas of the frontal lobes, the symptoms include a lack of drive and spontaneity. With damage to the most anterior aspects of the frontal lobes, the symptoms tend to involve more changes in mood and affect, such as impulsive and inappropriate behavior.

The skull of Phineas Gage, showing the route the tamping rod took through his skull. The angle of entry of the rod shot it behind the left eye and through the front part of the brain, sparing regions that are directly concerned with vital functions like breathing and heartbeat.

87Parietal Lobes

The postcentral gyrus, immediately behind the central sulcus, contains the primary somatosensory area. Damage to this area and neighboring gyri results in deficits in discriminative sensory function but not in the ability to perceive sensory input. The posterior areas of the parietal lobe appear to coordinate visual and somatosensory information. Damage to this area produces complex sensory deficits, including neglect of contralateral sensory stimuli and spatial relationships. The parietal lobes contribute to the ability to recognize objects by touch, calculate, write, recognize fingers of the opposite hands, draw, and organize spatial directions (e.g., how to travel to familiar places).

Temporal Lobes

The temporal lobes contain the primary auditory and olfactory areas. Wernicke area, located at the posterior aspect of the superior temporal gyrus, is primarily responsible for receptive speech. The temporal lobes also integrate sensory and visual information involved in control of written and verbal language skills as well as visual recognition. The hippocampus, an important structure discussed later, lies in the internal aspects of each temporal lobe and contributes to memory. Other internal structures of this lobe are involved in the modulation of mood and emotion.

Occipital Lobes

The primary visual area is in the most posterior aspect of the occipital lobes. Damage to this area results in a condition called *cortical blindness*. In other words, the retina and optic nerve remain intact, but the individual cannot see. The occipital lobes are involved in many aspects of visual integration of information, including color vision, object and facial recognition, and the ability to perceive objects in motion.

Association Cortex

Although not a lobe, the association cortex is an important area that allows the lobes to work in an integrated manner. Areas of one lobe of the cortex often share functions with an area of the adjacent lobe. When these neighboring nerve

fibers are related to the same sensory modality, they are often referred to as *association areas*. For example, an area in the inferior parietal, posterior temporal, and anterior occipital lobes integrates visual, somatosensory, and auditory information to provide the abilities required for basic academic skills. These areas, along with numerous connections beneath the cortex, are part of the mechanisms that allow the human brain to work as an integrated whole.

Subcortical Structures

Beneath the cortex are layers of tissue composed of the axons of cell bodies. The axonal tissue forms pathways that are surrounded by glia, a fatty or lipid substance, which has a white appearance, and give these layers of neuron axons their name—white matter. Structures inside the hemispheres, beneath the cortex, are considered subcortical. Many of these structures, essential in the regulation of emotions and behaviors, play important roles in our understanding of mental disorders. [Figure 8.2](#) provides a coronal section view of the gray matter, white matter, and important subcortical structures.

The **basal ganglia** are subcortical gray matter areas in both the right and the left hemispheres that contain many cell bodies or nuclei. The primary subdivisions of the basal ganglia are the putamen, globus pallidus, and caudate. The basal ganglia are involved with motor functions and the learning and the programming of behavior or activities that are repetitive and, done over time, become automatic. The basal ganglia have many connections with the cerebral cortex, thalamus, midbrain structures, and spinal cord. Damage to portions of these nuclei may produce changes in posture or muscle tone. In addition, damage may produce abnormal movements, such as twitches or tremors. The basal ganglia can be adversely affected by some of the medications used to treat psychiatric disorders, leading to side effects and other motor-related problems.

Limbic System

The **limbic system** is essential to understanding the many hypotheses related to psychiatric disorders and emotional behavior in general. The limbic system is called a “system” because it comprises several small structures that work in a highly organized way. These structures include the hippocampus, thalamus,

hypothalamus, amygdala, and limbic midbrain nuclei. See [Figure 8.3](#) for identification and location of the structures within the limbic system and their relationships to other common CNS structures.

Basic emotions, needs, drives, and instinct begin and are modulated in the limbic system. Hate, love, anger, aggression, and caring are basic emotions that originate within the limbic system. Not only does the limbic system function as the seat of emotions, but because emotions are often generated based on our personal experiences, the limbic system also is involved with aspects of memory. Hypothesized changes in the limbic system play a significant role in many theories of major mental disorders, including schizophrenia, depression, and anxiety disorders (discussed in later chapters).

FIGURE 8.2 Coronal section of the brain, illustrating the corpus callosum, basal ganglia, and lateral ventricles. (Reprinted with permission from Bear, M. F., Connors, B. W., & Paradiso, M. A. [2016]. *Neuroscience: Exploring the brain* [4th ed.]. Wolters Kluwer.)

FIGURE 8.3 The structures of the limbic system are integrally involved in memory and emotional behavior. Theories link changes in the limbic system to many major mental disorders, including schizophrenia, depression, and anxiety disorders.

Hippocampus

88The **hippocampus** is involved in storing information, especially the emotions attached to a memory. Our emotional responses to memories and our associations with other related memories are functions of how information is stored within the hippocampus. Although memory storage is not limited to one area of the brain, destruction of the left hippocampus impairs verbal memory, and damage to the right hippocampus results in difficulty with recognition and recall of complex visual and auditory patterns. Deterioration of the nerves of the hippocampus and other related temporal lobe structures found in Alzheimer disease produces the disorder's hallmark symptoms of memory dysfunction.

Thalamus

Sometimes called the “relay-switching center of the brain,” the thalamus

functions as a regulatory structure to relay all sensory information, except smell, sent to the CNS from the PNS. From the thalamus, the sensory information is relayed mostly to the cerebral cortex. The thalamus relays and regulates by filtering incoming information and determining what to pass on or not pass on to the cortex. In this fashion, the thalamus prevents the cortex from becoming overloaded with sensory stimulus. The thalamus is thought to play a part in controlling electrical activity in the cortex. Because of its primary relay function, damage to a very small area of the thalamus may produce deficits in many cortical functions, thus causing behavioral abnormalities.

Hypothalamus

Basic human activities, such as sleep–rest patterns, body temperature, and physical drives such as hunger and sex, are regulated by another part of the limbic system that rests deep within the brain and is called the hypothalamus. Dysfunction of this structure, whether from disorders or because of an adverse effect of drugs used to treat mental illness, produces common psychiatric symptoms, such as appetite and sleep problems.

Nerve cells within the hypothalamus secrete hormones, for example, antidiuretic hormone, which, when sent to the kidneys, accelerates the reabsorption of water; and oxytocin, which acts on smooth muscles to promote contractions, particularly within the walls of the uterus. Because cells within the nervous system produce these hormones, they are often referred to as **neurohormones** (hormones that are produced by cells within the nervous system) and form a communication mechanism through the bloodstream to control organs that are not directly connected to nervous system structures.

The pituitary gland, often called the *master gland*, is directly connected by thousands of neurons that attach it to the ventral aspects of the hypothalamus. Together with the pituitary gland, the hypothalamus functions as one of the primary regulators of many aspects of the endocrine system. Its functions are involved in control of visceral activities, such as body temperature, arterial blood pressure, hunger, thirst, fluid balance, gastric motility, and gastric secretions. Deregulation of the hypothalamus can be manifested in symptoms of certain psychiatric disorders. For example, in schizophrenia, patients often wear heavy coats during the hot summer months and do not appear hot. Before the role of the hypothalamus in schizophrenia was understood, psychological reasons were

used to explain such symptoms. Now it is increasingly clear that such a symptom relates to deregulation of the hypothalamus's normal role in temperature regulation and is a biologically based symptom (Tan & Knight, 2018).

Amygdala

The amygdala is directly connected to more primitive centers of the brain involving the sense of smell. It has numerous connections to the hypothalamus and lies adjacent to the hippocampus. The amygdala provides an emotional component to memory and is involved in modulating aggression and sexuality. Impulsive acts of aggression and violence have been linked to dysregulation of the amygdala, and erratic firing of the nerve cells in the amygdala is a focus of investigation in bipolar mood disorders (see Chapter 26).

Limbic Midbrain Nuclei

The limbic midbrain nuclei are a collection of neurons (including the ventral tegmental area and the locus coeruleus) that appear to play a role in the biologic basis of addiction. Sometimes referred to as the pleasure center or reward center of the brain, the limbic midbrain nuclei function to chemically reinforce certain behaviors, ensuring their repetition. Emotions such as feeling satisfied with good food, the pleasure of nurturing young, and the enjoyment of sexual activity originate in the limbic midbrain nuclei. The reinforcement of activities such as nutrition, procreation, and nurturing young are all primitive aspects of ensuring the survival of a species. When functioning in abnormal ways, the limbic midbrain nuclei can begin to reinforce unhealthy or risky behaviors, such as drug abuse. Exploration of this area of the brain is in its infancy but offers potential insight into addictions and their treatment.

Other Central Nervous System Structures

The **extrapyramidal motor system** is a bundle of nerve fibers connecting the thalamus to the basal ganglia and cerebral cortex. Muscle tone, common

reflexes, and automatic voluntary motor functioning (e.g., walking) are controlled by this nerve track. Dysfunction of this motor track can produce hypertonicity in muscle groups. In Parkinson disease, the cells that compose the extrapyramidal motor system are severely affected, producing many involuntary motor movements. A number of medications, which are discussed in [Chapter 12](#), also affect this system.

The **pineal body** is located above and medial to the thalamus. Because the pineal gland easily calcifies, it can be visualized by neuroimaging and often is a medial landmark. Its functions remain somewhat of a mystery despite long knowledge of its existence. It contains secretory cells that emit the neurohormone melatonin and other substances. These hormones are thought to have several regulatory functions within the endocrine system. Information received from light–dark sources controls release of melatonin, which has been associated with sleep and emotional disorders. In addition, a modulation of immune function has been postulated for melatonin from the pineal gland.

The **locus coeruleus** is a tiny cluster of neurons that fan out and innervate almost every part of the brain, including 90% of the cortex, the thalamus and hypothalamus, the **cerebellum**, and the spinal cord. Just one neuron from the coeruleus can connect to more than 250,000 other neurons. Despite its small size, the wide-ranging neuronal connections allow this tiny structure to influence the regulation of attention, time perception, sleep–rest cycles, arousal, learning, pain, and mood. It also plays a role in information processing of new, unexpected, and novel experiences. Some think its function or dysfunction may explain why individuals become addicted to substances and seek out risky behaviors despite awareness of negative consequences.

The brain stem, which is located beneath the thalamus and composed of the midbrain, pons, and medulla, has important life-sustaining functions. Nuclei of numerous neural pathways to the cerebrum are in the brain stem. They are significantly involved in mediating symptoms of emotional dysfunction. These nuclei are also the primary source of several neurochemicals, such as serotonin, that are commonly associated with psychiatric disorders.

The cerebellum is in the posterior aspect of the skull beneath the cerebral hemispheres. This large structure controls movements and postural adjustments. To regulate postural balance and positioning, the cerebellum receives information from all parts of the body, including the muscles, joints, skin, and visceral organs, as well as from many parts of the CNS.

Autonomic Nervous System

Closely associated with the spinal cord but not lying entirely within its column is the **autonomic nervous system**, a subdivision of the PNS. It was originally given this name for being independent of conscious thought, that is, automatic. However, it does not necessarily function as autonomously as the name indicates. This system contains efferent (nerves moving away from the CNS), or motor system neurons, which affect target tissues such as cardiac muscle, smooth muscle, and the glands. It also contains afferent nerves, which are sensory and conduct information from these organs back to the CNS.

The autonomic nervous system is further divided into the sympathetic and parasympathetic nervous systems. These systems, although peripheral, are included here because they are involved in the emergency, or “fight-or-flight,” response as well as the peripheral actions of many medications (see [Chapter 12](#)). [Figure 8.4](#) illustrates the innervations of various target organs by the autonomic nervous system. [Table 8.1](#) identifies the actions of the sympathetic and parasympathetic nervous systems on various target organs.

TABLE 8.1 PERIPHERAL ORGAN RESPONSE IN THE AUTONOMIC NERVOUS SYSTEM

Effector Organ	Sympathetic Response (Mostly Norepinephrine)	Parasympathetic Response (Acetylcholine)
Eye		
• Iris sphincter muscle	Dilation	Constriction
• Ciliary muscle	Relaxation	Accommodation for near vision
Heart		
• Sinoatrial node	Increased rate	Decrease in rate
• Atria	Increased contractility	Decrease in contractility
• Atrioventricular node	Increased contractility	Decrease in conduction velocity
Blood Vessels	Constriction	Dilation

<i>Lungs</i>		
• Bronchial muscles	Relaxation	Bronchoconstriction
• Bronchial glands		Secretion
<i>Gastrointestinal Tract</i>		
• Motility and tone	Relaxation	Increased
• Sphincters	Contraction	Relaxation
• Secretion		Stimulation
<i>Urinary Bladder</i>		
• Detrusor muscle	Relaxation	Contraction
• Trigone and sphincter	Contraction	Relaxation
<i>Uterus</i>	Contraction (pregnant) Relaxation (nonpregnant)	Variable
<i>Skin</i>		
• Pilomotor muscles	Contraction	No effect
• Sweat glands	Increased secretion	No effect
<i>Glands</i>		
• Salivary, lachrymal		Increased secretion
• Sweat		Increased secretion

NEUROPHYSIOLOGY OF THE CENTRAL NERVOUS SYSTEM

At their most basic level, the human brain and connecting nervous system are composed of billions of cells. Most are connective and supportive glial cells with ancillary functions in the nervous system.

FIGURE 8.4 Diagram of the autonomic nervous system. Note that many organs are innervated by both sympathetic and parasympathetic nerves. *Note.* ACh = acetylcholine; NE = norepinephrine. (Reprinted with permission from Bear, M. F., Connors, B. W., & Paradiso, M. A. [2016]. *Neuroscience: Exploring the brain* [4th ed.]. Wolters Kluwer.) *Note.* ACh = acetylcholine; NE = norepinephrine.

92KEYCONCEPT Neuroplasticity is a continuous process of modulation of neuronal structure and function in response to the changing environment.

The changes in neural environment can come from internal sources, such as a change in electrolytes, or from external sources, such as a virus or toxin. Because of neuroplasticity, nerve signals may be rerouted, cells may learn new functions, the sensitivity or number of cells may increase or decrease, and some nerve tissue may undergo limited regeneration. Brains are mostly plastic during infancy and young childhood, when large adaptive learning tasks should normally occur. With age, brains become less plastic, which explains why it is

easier to learn a second language at the age of 5 years than 55 years. Neuroplasticity contributes to understanding how function may be restored over time after brain damage occurs, or how an individual may react over time to continuous pharmacotherapy regimens.

FIGURE 8.5 Cell body and organelles of neuron. *Note.* CNS = central nervous system; PNS = peripheral nervous system.

Neurons and Nerve Impulses

In the human body, approximately 10 billion nerve cells, or neurons, function to receive, organize, and transmit information (Fig. 8.5). Each neuron has a cell body, or soma, which holds the nucleus containing most of the cell's genetic information. The soma also includes other organelles, such as ribosomes and endoplasmic reticulum, which carry out protein synthesis; the Golgi apparatus, which contains enzymes to modify the proteins for specific functions; vesicles, which transport and store proteins; and lysosomes, which are responsible for degradation of these proteins. Located throughout the neurons, mitochondria, containing enzymes and often called the “powerhouse,” are the sites of many energy-producing chemical reactions. These cell structures provide the basis for secreting numerous chemicals by which neurons communicate.

It is not just the vast number of neurons that accounts for the complexities of the brain but also the enormous number of neurochemical interconnections

and interactions among neurons. A single motor neuron in the spinal cord may receive signals from more than 10,000 sources of interconnections with other nerves. Although most neurons have only one axon, which varies in length and conducts impulses away from the soma, each has numerous dendrites, receiving signals from other neurons. Because axons may branch as they terminate, they also have multiple contacts with other neurons.

Nerve signals are prompted to fire by a variety of chemical or physical stimuli. This firing produces an electrical impulse. The cell's membrane is a double layer of phospholipid molecules with embedded proteins. Some of these proteins provide water-filled channels through which inorganic ions may pass (Fig. 8.6). Each of the common ions—sodium, potassium, calcium, and chloride—has its own specific molecular channel. Many of these channels are voltage gated and thus open or close in response to changes in the electrical potential across the membrane. At rest, the cell membrane is polarized with a positive charge on the outside and about a 270 mV charge on the inside, owing to the resting distribution of sodium and potassium ions. As potassium passively diffuses across the membrane, the sodium pump uses energy to move sodium from the inside of the cell against a concentration gradient to maintain this distribution. An action potential, or *nerve impulse*, is generated as the membrane is depolarized and a threshold value is reached, which triggers the opening of the voltage-gated sodium channels, allowing sodium to surge into the cell. The inside of the cell briefly becomes positively charged and the outside negatively charged. Once initiated, the action potential becomes self-propagating, opening nearby sodium channels. This electrical communication moves into the soma from the dendrites or down the axon by this mechanism.

FIGURE 8.6 Initiation of a nerve impulse. The initiation of an action potential, or nerve impulse, involves the opening and closing of the voltage-gated channels on the cell membrane and the passage of ions into the cell. The resulting electrical activity sends communication impulses from the dendrites or axon into the body.

Synaptic Transmission

For one neuron to communicate with another, the electrical process described must change to a chemical communication. The **synaptic cleft**, a junction between one nerve and another, is the space where the electrical intracellular signal becomes a chemical extracellular signal. Various substances are recognized as the chemical messengers among neurons.

As the electrical action potential reaches the ends of the axons, called *terminals*, calcium ion channels are opened, allowing an influx of Ca^{++} ions into the neuron. This increase in calcium stimulates the release of neurotransmitters into the synapse. Rapid signaling among neurons requires a ready supply of neurotransmitter. These neurotransmitters are stored in small vesicles grouped near the cell membrane at the end of the axon. When stimulated, the vesicles containing the neurotransmitter fuse with the cell membrane, and the neurotransmitter is released into the synapse (Fig. 8.7). The neurotransmitter then crosses the synaptic cleft to a receptor site on the postsynaptic neuron and stimulates adjacent neurons. This is the process of neuronal communication.

When the neurotransmitter has completed its interaction with the postsynaptic receptor and stimulated that cell, its work is done, and it needs to be removed. It can be removed by natural diffusion away from the area of high neurotransmitter concentration at the receptors by being broken down by enzymes in the synaptic cleft or through reuptake through highly specific mechanisms into the presynaptic terminal. The primary steps in synaptic transmission are summarized in Figure 8.7.

Neurotransmitters

As described in the overview earlier, neurotransmitters are key in the process of synaptic transmission. 94Neurotransmitters are small molecules that directly and indirectly control the opening or closing of ion channels. **Neuromodulators** are chemical messengers that make the target cell membrane or postsynaptic membrane susceptible to the effects of the primary neurotransmitter.

FIGURE 8.7 Synaptic transmission. The most significant events that occur during synaptic transmission are as follows: (1) the action potential reaches the presynaptic terminal; (2) membrane depolarization causes Ca^{++} terminals to open; (3) Ca^{++} mediates fusion of the vesicles with the presynaptic membrane; (4) transmitter molecules are released into the synaptic cleft by exocytosis; (5)

transmitter molecules bind to postsynaptic receptors and activate ion channels; (6) conductance changes cause an excitatory or inhibitory postsynaptic potential, depending on the specific transmitter; (7) current flow spreads along the postsynaptic membrane; (8) transmitter remaining in the synaptic cleft returns to the presynaptic terminal by reuptake; and (9) the transmitter diffuses into the extracellular fluid.

Note. AMP, adenosine monophosphate; ATP, adenosine triphosphate; cAMP, cyclic adenosine monophosphate; GDP, guanosine diphosphate; GTP, guanosine triphosphate. (Reprinted with permission from Bear, M. F., Connors, B. W., & Paradiso, M. A. [2016]. *Neuroscience: Exploring the brain* [4th ed.]. Wolters Kluwer.)

KEYCONCEPT Neurotransmitters are small molecules that directly and indirectly control the opening or closing of ion channels.

Excitatory neurotransmitters reduce the membrane potential and enhance the transmission of the signal between neurons. *Inhibitory neurotransmitters* have the opposite effect and slow down nerve impulses. Although some are synthesized from dietary precursors, such as tyrosine or tryptophan, most synthesis occurs in the terminals or the neuron itself. Neurotransmitters are commonly classified as the following: cholinergic, biogenic amine (monoamines or bioamines), amino acid, and neuropeptides. [Table 8.2](#) summarizes some of the key neurotransmitters and their proposed functions.

Acetylcholine

Acetylcholine (ACh) is the primary cholinergic neurotransmitter. Found in the greatest concentration in the PNS, ACh provides the basic synaptic communication for the parasympathetic neurons and part of the sympathetic neurons, which send information to the CNS.

ACh is an excitatory neurotransmitter that is found throughout the cerebral cortex and limbic system. It arises primarily from cell bodies in the basal forebrain constellation, which provides innervations to the cerebral cortex, amygdala, hippocampus, and thalamus as well as from the dorsolateral tegmentum of the pons that projects to the basal ganglia, thalamus, hypothalamus, medullary reticular formation, and deep cerebellar nuclei ([Fig.](#)

8.8) (Colangelo et al., 2019). These connections suggest that ACh is involved in higher intellectual functioning and memory. Individuals who have Alzheimer disease or Down syndrome often exhibit patterns of cholinergic neuron loss in regions innervated by these pathways (e.g., the hippocampus), which may contribute to their memory difficulties and other cognitive deficits. Some cholinergic neurons are afferent to these areas bringing information from the limbic system, highlighting the role that ACh plays in communicating one's emotional state to the cerebral cortex.

**TABLE 8.2 95CLASSIC AND PUTATIVE
NEUROTRANSMITTERS: THEIR
DISTRIBUTION AND PROPOSED FUNCTIONS**

Neurotransmitter	Cell Bodies	Projections	Proposed Function
<i>Acetylcholine</i>			
Dietary precursor: choline	Basal forebrain Pons Other areas	Diffuse throughout the cortex,hippocampus PNS	Important role in learning and memory Some role in wakefulness and basic attention Peripherally activates muscles and is the major neurochemical in the autonomic system
<i>Monoamines</i>			
Dopamine (dietary precursor: tyrosine)	Substantia nigra Ventral tegmental area Arcuate	Striatum (basal ganglia) Limbic system and cerebral cortex Pituitary	Involved in involuntary motor movements Some role in

	nucleus Retina olfactory bulb		mood states, pleasure components in reward systems and complex behavior(e.g., judgment, reasoning, insight)
Norepinephrine (dietary precursor: tyrosine)	Locus coeruleus Lateral tegmental area and others throughout the pons and medulla	Very widespread throughout the cortex, thalamus, cerebellum, brain stem, and spinal cord Basal forebrain, thalamus, hypothalamus, brain stem, and spinal cord	Proposed role in learning and memory, attributing value in reward systems, fluctuates in sleep and wakefulness Major component of the sympathetic nervous system responses, including “fight or flight”
Serotonin (dietary precursor:tryptophan)	Raphe nuclei Others in the pons and medulla	Very widespread throughout the cortex, thalamus, cerebellum, brain stem, and spinal cord	Proposed role in the control of appetite, sleep, mood states, hallucinations, pain perception and vomiting
Histamine(precursor:histidine)	Hypothalamus	Cerebral cortex Limbic system Hypothalamus Found in all mast cells	Control of gastric secretions, smooth muscle control, cardiac stimulation, stimulation of

sensory nerve endings, and alertness

Amino Acids

GABA	Derived from glutamate without localized cell bodies	Found in cells and projections throughout the CNS, especially in intrinsic feedback loops and interneurons of the cerebrum; also in the extrapyramidal motor system and cerebellum	Fast inhibitory response postsynaptically inhibits the excitability of the neurons and therefore contributes to seizure, agitation, and anxiety control
Glycine	Primarily the spinal cord and brain stem	Limited projection, but especially in the auditory system and olfactory bulb Also found in the spinal cord, medulla, midbrain, cerebellum, and cortex	Inhibitory Decreases the excitability of spinal motor neurons but not cortical
Glutamate	Diffuse	Diffuse, but especially in the sensory organs	Excitatory Responsible for the bulk of information flow

Neuropeptides

Endogenous opioids (i.e., endorphins, enkephalins)	A large family of neuropeptides that has three distinct subgroups, all of which are	Widely distributed within and outside of the CNS	Suppress pain, modulate mood and stress Likely involvement in reward systems and addiction
--	---	--	---

	manufactured widely throughout the CNS		Also may regulate pituitary hormone release. Implicated in the pathophysiology of diseases of the basal ganglia.
Melatonin (one of its precursors: serotonin)	Pineal body	Widely distributed within and outside of the CNS	Secreted in darkness and suppressed in light, helps regulate the sleep–wake cycle as well as other biologic rhythms.
Substance P	Widespread, significant in the raphe system and spinal cord	Spinal cord, cortex, brain stem, and especially sensory neurons associated with pain perception	Involved in pain transmission, movement, and mood regulation.
Cholecystokinin	Predominates in the ventral tegmental area of the midbrain	Frontal cortex, where it is often colocalized with dopamine. Widely distributed within and outside of the CNS.	Primary intestinal hormone involved in satiety; also has some involvement in the control of anxiety and panic.

Note. CNS = central nervous system; GABA = gamma-aminobutyric acid; PNS = peripheral nervous system.

FIGURE 8.8 Cholinergic pathways. (Reprinted with permission from Bear, M. F., Connors, B. W., & Paradiso, M. A. [2016]. *Neuroscience: Exploring the brain* [4th ed.]. Wolters Kluwer.)

Biogenic Amines

96The **biogenic amines** (bioamines) consist of small molecules manufactured in the neuron that contain an amine group, thus the name. The catecholamines (amine attached to a catechol group) include dopamine, norepinephrine, and epinephrine, which are all synthesized from the amino acid tyrosine. Another monoamine, serotonin, is synthesized from tryptophan. Melatonin is derived from serotonin. All of these neurotransmitters are critical in many of the mental disorders.

Dopamine

Dopamine is an excitatory neurotransmitter found in distinct regions of the CNS and is involved in cognition, motor, and neuroendocrine functions. Dopamine is the neurotransmitter that stimulates the body's natural "feel good" reward pathways, producing pleasant euphoric sensation under certain conditions. It is involved in the regulation of action, emotion, motivation, and attention.

Dopamine levels are decreased in Parkinson disease, and abnormally high activity of dopamine has been associated with schizophrenia (discussed in more detail in [Chapter 24](#)). Abnormalities of dopamine activity within the reward system pathways are suspected to be a critical aspect of the development of drug and other addictions. The dopamine pathways are distinct neuronal areas within the CNS in which the neurotransmitter dopamine predominates. Three major dopaminergic pathways have been identified.

The *mesocortical* and *mesolimbic pathways* originate in the ventral tegmental area and project into the medial aspects of the cortex (mesocortical) and the limbic system inside the temporal lobes, including the hippocampus and amygdala (mesolimbic). Sometimes, they are considered to be one pathway and at other times two separate pathways. The mesocortical pathway has major effects on cognition, including functions such as judgment, reasoning, insight, social conscience, motivation, the ability to generalize learning, and reward systems in the human brain. It contributes to some of the highest seats of cortical functioning. The mesolimbic pathway also strongly influences emotions and has projections that affect memory and auditory reception. Abnormalities in these pathways have been associated with schizophrenia.

Another major dopaminergic pathway begins in the substantia nigra and projects into the basal ganglia, parts of which are known as the *striatum*. Therefore, this pathway is called the *nigrostriatal pathway*. This influences the extrapyramidal motor system, which serves the voluntary motor system and allows involuntary motor movements. Destruction of dopaminergic neurons in this pathway has been associated with Parkinson disease.

The final dopamine pathway originates from projections of the mesolimbic pathway and continues into the hypothalamus, which then projects into the pituitary gland. Therefore, this pathway, called the *tuberoinfundibular pathway*, has an impact on endocrine function and other functions, such as metabolism, hunger, thirst, sexual function, circadian rhythms, digestion, and temperature control. [Figure 8.9](#) illustrates the dopaminergic pathways.

Norepinephrine

Norepinephrine is an excitatory neurochemical that plays a major role in generating and maintaining mood states. Because norepinephrine is so heavily concentrated in the terminal sites of sympathetic nerves, it can be released quickly to ready the individual for a fight-or-flight response to threats in the

environment. For this reason, norepinephrine is thought to play a role in the physical symptoms of anxiety (Bastos et al., 2018).

Nerve tracts and pathways containing predominantly norepinephrine are called *noradrenergic* and are less clearly delineated than the dopamine pathways. In the CNS, noradrenergic neurons originate in the locus coeruleus, where more than half of the noradrenergic cell bodies are located. Because the locus coeruleus is one of the major timekeepers of the human body, norepinephrine is involved in sleep and wakefulness. From the locus coeruleus, noradrenergic pathways ascend into the neocortex, spread diffusely (Fig. 8.10), and enhance the ability of neurons to respond to whatever input they may be receiving. In addition, norepinephrine appears to be involved in the process of reinforcement, which facilitates learning. Noradrenergic pathways innervate the hypothalamus and thus are involved to some degree in endocrine function. Anxiety disorders and depression are examples of psychiatric illnesses in which dysfunction of the noradrenergic neurons may be involved. (Refer to Table 8.1 for the effects of ACh on various organs in the parasympathetic system.)

FIGURE 8.9 Dopaminergic pathways. C, caudate nucleus; H, hypothalamus;

HC, hippocampal formation; P, putamen; S, striatum; V, ventral striatum. The dopaminergic diffuse modulatory systems arising from the substantia nigra and the ventral tegmental area. The substantia nigra and ventral tegmental area lie close together in the midbrain. The project to the striatum (caudate nucleus and putamen) and limbic and frontal cortical regions, respectively. FIGURE 8.10 Noradrenergic pathways. (Reprinted with permission from Bear, M. F., Connors, B. W., & Paradiso, M. A. [2016]. *Neuroscience: Exploring the brain* [4th ed.]. Wolters Kluwer.)

Serotonin

Serotonin (also called 5-hydroxytryptamine or 5-HT) is primarily an excitatory neurotransmitter that is diffusely distributed within the cerebral cortex, limbic system, and basal ganglia of the CNS. Serotonergic neurons also project into the hypothalamus and cerebellum. [Figure 8.11](#) illustrates serotonergic pathways. Serotonin plays a role in emotions, cognition, sensory perceptions, and essential biologic functions, such as sleep and appetite. During the rapid eye movement

(REM) phase of sleep, or the dream state, serotonin concentrations decrease, and muscles subsequently relax. Serotonin is also involved in the control of food intake, hormone secretion, sexual behavior, thermoregulation, and cardiovascular regulation. Some serotonergic fibers reach the cranial blood vessels within the brain and the *pia mater* where they have a vasoconstrictive effect. The potency of some new medications for migraine headaches is related to their ability to block serotonin transmission in the cranial blood vessels. Descending serotonergic pathways are important in central pain control. Whereas depression and insomnia have been associated with decreased levels of 5-HT, mania has been associated with increased 5-HT. Some of the most well-known antidepressant medications, such as Prozac and Zoloft, which are discussed in more depth in [Chapter 12](#), function by raising serotonin levels within certain areas of the CNS. Melatonin, which is derived from serotonin, is produced by the pineal gland and plays a role in sleep, aging, and mood changes.

FIGURE 8.11 The serotonergic diffuse modulatory systems arising from the raphe nuclei. The raphe nuclei are clustered along the midline of the brain stem and project extensively to all levels of the central nervous system. (Reprinted with permission from Bear, M. F., Connors, B. W., & Paradiso, M. A. [2016]. *Neuroscience: Exploring the brain* [4th ed.]. Wolters Kluwer.)

Amino Acids

Amino acids, the building blocks of proteins, have many roles in intraneuronal metabolism. In addition, amino acids can function as neurotransmitters in as many as 60% to 70% of the synaptic sites in the brain. Amino acids are the most prevalent neurotransmitters. Virtually all of the neurons in the CNS are activated by excitatory amino acids, such as glutamate, and inhibited by inhibitory amino acids, such as **gamma-aminobutyric acid (GABA)** and glycine. Many of these amino acids coexist with other neurotransmitters.

Histamine

Histamine, derived from the amino acid histidine, has been identified as a neurotransmitter. Its cell bodies originate predominantly in the hypothalamus and project to all major structures in the cerebrum, brain stem, and spinal cord. Its functions are not well known, but it appears to have a role in autonomic and neuroendocrine regulation. Many psychiatric medications can block the effects of histamine postsynaptically and produce side effects such as sedation, weight gain, and hypotension.

Gamma-Aminobutyric Acid

GABA is the primary inhibitory neurotransmitter for the CNS. The pathways of GABA exist almost exclusively in the CNS, with the largest GABA concentrations in the hypothalamus, hippocampus, basal ganglia, spinal cord, and cerebellum. GABA functions in an inhibitory role in control of spinal reflexes and cerebellar reflexes. It has a major role in the control of neuronal excitability through the brain. In addition, GABA has an inhibitory influence on the activity of the dopaminergic nigrostriatal projections. GABA also has interconnections with other neurotransmitters. For example, dopamine inhibits cholinergic neurons, and GABA provides feedback and balance. Dysregulation of GABA and GABA receptors has been associated with anxiety disorders, and decreased GABA activity is involved in the development of seizure disorders.

Glutamate

Glutamate, the most widely distributed excitatory neurotransmitter, is the main transmitter in the associational areas of the cortex. Glutamate can be found in a number of pathways from the cortex to the thalamus, pons, striatum, and spinal cord. In addition, glutamate pathways have a number of connections with the hippocampus. Some glutamate receptors may play a role in the long-lasting enhancement of synaptic activity. In turn, in the hippocampus, this enhancement may have a role in learning and memory. Too much glutamate is harmful to neurons, and considerable interest has emerged regarding its neurotoxic effects.

Conditions that produce an excess of endogenous glutamate can cause neurotoxicity by overexcitation of neuronal tissue. This process, called excitotoxicity, increases the sensitivity of glutamate receptors, produces overactivation of the receptors, and is increasingly being understood as a critical piece of the cascade of events involved in physical symptoms of alcohol withdrawal in dependent individuals. Excitotoxicity is also believed to be part of the pathology of conditions such as ischemia, hypoxia, hypoglycemia, and hepatic failure. Damage to the CNS from chronic malfunctioning of the glutamate system may be involved in the psychiatric symptoms seen in neurodegenerative diseases such as Huntington, Parkinson, and Alzheimer diseases; vascular dementia; amyotrophic lateral sclerosis; and AIDS-related dementia. Degeneration of glutamate neurons is implicated in the development of schizophrenia.

Neuropeptides

Neuropeptides, short chains of amino acids, exist in the CNS and have a number of important roles as neurotransmitters, neuromodulators, or neurohormones. Neuropeptides were first thought to be pituitary hormones, such as adrenocorticotropin, oxytocin, and vasopressin, or hypothalamic-releasing hormones (e.g., corticotropin-releasing hormone and thyrotropin-releasing hormone). However, when an endogenous morphine-like substance was discovered in the 1970s, the term *endorphin*, or endogenous morphine, was introduced. Although the amino acids and monoamine neurotransmitters can be produced directly from dietary precursors in any part of the neuron, neuropeptides are, almost without exception, synthesized from messenger ribonucleic acid in the cell body. Currently, two types of neuropeptides have been identified. Opioid neuropeptides, such as endorphins, enkephalins, and

dynorphins, function in endocrine functioning and pain suppression. The nonopioid neuropeptides, such as substance P and somatostatin, play roles in pain transmission and endocrine functioning, respectively.

99There are considerable variations in the distribution of individual neuropeptides, but some areas are especially rich in cell bodies containing neuropeptides. These areas include the amygdala, striatum, hypothalamus, raphe nuclei, brain stem, and spinal cord. Many of the interneurons of the cerebral cortex contain neuropeptides, but there are considerably fewer in the thalamus and almost none in the cerebellum.

Receptors

Embedded in the postsynaptic membrane are a number of proteins that act as receptors for the released neurotransmitters. Each neurotransmitter has a specific receptor, or protein, for which it and only it will fit.

Lock and Key

The “lock-and-key” analogy has often been used to describe the fit of a given neurotransmitter to its receptor site. The target cell, when stimulated by the neurotransmitter, will then respond by evoking its own action potential and either producing some action common to that cell or acting as a relay to keep the messages moving throughout the CNS. This pattern of the electrical signal from one neuron, converted to chemical signal at the synaptic cleft, picked up by an adjacent neuron, again converted to an electrical action potential, and then to a chemical signal, occurs billions of times a day in billions of different neurons. This electrical–chemical communication process allows the structures of the brain to function together in a coordinated and organized manner.

Receptor Sensitivity

Both presynaptic and postsynaptic **receptors** have the capacity to change, developing either a greater-than-usual response to the neurotransmitter, known

as supersensitivity, or a less-than-usual response, called subsensitivity. These changes represent the concept of neuroplasticity of brain tissue discussed earlier in the chapter. The change in sensitivity of the receptor is most commonly caused by the effect of a drug on a receptor site or by disease that affects the normal functioning of a receptor site. Drugs can affect the sensitivity of the receptor by altering the strength of attraction or affinity of a receptor for the neurotransmitter, by changing the efficiency with which the receptor activity translates the message inside the receiving cell, or by decreasing over time the number of receptors.

These mechanisms may account for the long-term, sometimes severely adverse, effects of psychopharmacologic drugs, the loss of effectiveness of a given medication, or the loss of effectiveness of a medication after repeated use in treating recurring episodes of a psychiatric disorder. Disease may cause a change in the normal number or function of receptors, thereby altering their sensitivity. For example, depression is associated with a reduction in the normal number of certain receptors, leading to an abnormality in their sensitivity to neurotransmitters such as serotonin and norepinephrine (Crispino et al., 2020). A decreased response to continued stimulation of these receptors is usually referred to as *desensitization* or *refractoriness*. This suspected subsensitivity is referred to as *downregulation* of the receptors.

Receptor Subtypes

The nervous system uses many different neurochemicals for communication, and each specific chemical messenger requires a specific receptor on which the chemical can act. More than 100 different chemical messengers have been identified, with new ones being uncovered. In addition to the sheer number of receptors needed to accommodate these chemicals, the neurotransmitters may produce different effects at different synaptic sites.

Each major neurotransmitter has several different subtypes of receptors, allowing the neurotransmitter to have different effects in different areas of the brain. The receptors usually have the same name as the neurotransmitter, but the classification of the subtypes varies. For example, dopamine receptors are named D1, D2, D3, and so on. Serotonin receptors are grouped in families such as 5HT 1a and 5HT 1b. The receptors for Ach have completely different names: muscarinic and nicotinic. Two specific subtype receptors have been identified for

GABA: A and B (see [Table 8.3](#)).

Brain structures such as the prefrontal cortex, striatum, hippocampus, and amygdala are linked through complex neural functional networks (Uddin et al., 2019). Recent research indicates that a dysfunctional **neurocircuitry** underlies most psychiatric disorders ([Fig. 8.12](#)). Various neurocircuits are the focus of study of different illness. For example, the cingulo-frontal-parietal network is associated with attention-deficit disorder, and the amygdalocortical circuitry is the focus in psychosis and schizophrenia.

TABLE 8.3 SELECTED NEUROTRANSMITTERS AND RECEPTORS

Neurotransmitter	Receptor Subtypes
Acetylcholine (ACH)	Muscarinic receptors (M ₁ , M ₂ , M ₃ , M ₄ , M ₅) Nicotinic receptor
Glutamate (Glu)	AMPA, NMDA, kainate receptors
Gamma-aminobutyric acid (GABA)	GABA _A , GABA _B
Serotonin (5-HT)	5-HT _{1A} , 5-HT _{1B} , 5-HT _{1D} , 5-HT _{1E} , 5-HT _{2A} , 5-HT _{2B} , 5-HT _C , 5-HT ₄ , 5-HT _{5A}
Dopamine (DA)	D1, D2, D3, D4, D5
Norepinephrine (NE)	α_1 , α_2 , β_1 , β_2

STUDIES OF THE BIOLOGIC BASIS OF MENTAL DISORDERS

As described earlier, mental disorders are complex syndromes consisting of clusters of biopsychosocial symptoms. These syndromes are not specific physiologic disorders, and research efforts are focused on piecing the puzzle together. One important area of study is genetics; it is well established that genetic factors play an important role in the development of mental disorders. In addition, as the complexity of the nervous system and its interrelationship with

other body systems and the environment have become more fully understood, new fields of study have emerged. One field worth noting is **psychoneuroimmunology (PNI)**. Although it has long been observed that individuals under stress have compromised immune systems and are more likely to acquire common diseases, only recently have changes in the immune system been noted as widespread in some psychiatric illnesses. Another field, **chronobiology**, has provided new information suggesting that dysfunction of biologic rhythms may not only result from a psychiatric illness but also contribute to its development.

Genetics

The sequence of the human genome is the beginning of our understanding of complex genetic connections that leads to a **phenotype** or observable characteristics or expressions of a specific trait. The genome provides researchers with a road map of the exact sequence of the three billion nucleotide bases that make up human organisms. Many thought that after the human genome was mapped, it would be easy to determine the genes responsible for mental disorders. Unfortunately, it is not that simple. Knowing the location of the gene and its sequence is just a piece of the complex puzzle. The location of the genes does not tell us which genes are responsible for a mental illness or how mutations occur.

Population Genetics

Inheritance of mental disorders is studied by using epidemiologic methods that identify risks and patterns of illness or traits from generation to generation. Beginning with a **proband**, a person who has the disorder or trait, **population genetics** relies on the following principal epidemiologic methods:

- **Family studies** analyze the occurrence of a disorder in first-degree relatives (biologic parents, siblings, and children), second-degree relatives (grandparents, uncles, aunts, nieces, nephews, and grandchildren), and so on.
- **Twin studies** analyze the presence or absence of the disorder in pairs of twins. The *concordance rate* is the measure of similarity of occurrence in

individuals with a similar genetic makeup.

- **Adoption studies** compare the risk for the illness developing in offspring raised in different environments. The strongest inferences may be drawn from studies that involve children separated from their parents at birth.

Mental disorders and their symptoms are not an expression of a single gene. The transmission pattern does not follow classic Mendelian genetics in which the dominant allele (variant) on only one chromosome or recessive alleles on both chromosomes are responsible for manifestation of a disorder. Monozygotic (identical) twins do not manifest the same mental disorder with 100% concordance rate, but they have a higher rate of a disorder than dizygotic (fraternal) twins, who share roughly the same proportion of genes that ordinary siblings do (50%). Internal and external environmental events influence the development of a disorder with a genetic contribution. This interaction between the environment and a genetic predisposition underlies several mental disorders such as schizophrenia, autism, and attention-deficit hyperactivity disorder.

Molecular Genetics

A gene comprises short segments of deoxyribonucleic acid and is packed with the instructions for making proteins that have a specific function. When genes are absent or malfunction, protein production is altered, and bodily functions are disrupted. In this fashion, genes play a role in cancer, heart disease, diabetes, and many psychiatric disorders. Although no conclusive evidence exists for a complete genetic cause of most psychiatric disorders, significant evidence suggests that strong genetic contributions exist for most (McCutcheon et al., 2020).

Intracellular genes direct protein production responsible for genetic expression. Individual nerve cells outside of the cell respond to these changes, modifying proteins to adapt to the new environment. This dynamic nature of gene function highlights the manner in which the body and the environment interact and in how environmental factors influence gene expression.

The study of molecular genetics in psychiatric disorders is in its infancy. It is likely that psychiatric disorders are polygenic. This means that psychiatric disorders develop when genes interact with each other and with environmental factors such as stress, infections, poor nutrition, catastrophic loss, complications during pregnancy, and exposure to toxins. Thus, genetic makeup conveys

vulnerability, or a risk for the illness, but the right set of environmental factors must be present for the disorder to develop in an at-risk individual (Renzi et al., 2018).

Genetic Susceptibility

The concept of **genetic susceptibility** suggests that an individual may be at increased risk for a psychiatric disorder. Specific risk factors for psychiatric disorders are just beginning to be understood, and environmental influences are examples of risk factors. In the absence of one specific gene for the major psychiatric disorders, risk factor assessment is a logical alternative for predicting who is more likely to experience psychiatric disorders or certain conditions, such as aggression or suicidality (Musci et al., 2019).

When considering information regarding risks for genetic transmission of psychiatric disorders, there are several key points to remember:

- Psychiatric disorders have been described and labeled quite differently across generations, and errors in diagnosis may occur.
- Similar psychiatric symptoms may have considerably different causes, just as symptoms such as chest pain may occur in relation to many different causes.
- Genes that are present may not always cause the appearance of the trait.
- Several genes work together in an individual to produce a given trait or disorder.
- A biologic cause is not necessarily solely genetic in origin. Environmental influences alter the body's functioning and often mediate or worsen genetic risk factors.

Psychoneuroimmunology

PNI examines the relationships among the immune system, nervous system, and endocrine system and our behaviors, thoughts, and feelings. The immune system is composed of the thymus, spleen, lymph nodes, lymphatic vessels, tonsils, adenoids, and bone marrow, which manufacture all the cells that eventually develop into T cells, B cells, phagocytes, macrophages, and natural killer (NK) cells ([Fig. 8.13](#)). Many contemporary stress research studies are examining the role of the NK cells in the early recognition of foreign bodies. Lower NK cell function is related to increased disease susceptibility. NK cell function is affected by stress-induced physiologic arousal in humans. NK cell activity has been shown to vary in response to many emotional, cognitive, and physiologic stressors, including anxiety, depression, perceived lack of personal control, bereavement, pain, and surgery (Costello et al., 2019; Furtado & Katzman, 2015).

Immune system

FIGURE 8.13 The immune system.

Overactivity of the immune system can occur in autoimmune diseases such as systemic lupus erythematosus, allergies, and anaphylaxis. Evidence suggests that the nervous system regulates many aspects of immune function. Specific

immune system dysfunctions may result from damage to the hypothalamus, hippocampus, or pituitary and may produce symptoms of psychiatric disorders. [Figure 8.14](#) illustrates the interaction between stress and the immune system. This figure also demonstrates the true biopsychosocial nature of the complex interrelationship of the nervous system, the endocrine system, the immune system, and environmental or emotional stress.

FIGURE 8.12 Examples of the interaction between stress or psychiatric illness and the immune system through the endocrine system. *Note.* ACTH = adrenocorticotrophic hormone; CRH = corticotropin-releasing hormone; FSH = follicle-stimulating hormone; IL = interleukin; LH = luteinizing hormone; TNF = tumor necrosis factor.

Immune dysregulation may also be involved in the development of psychiatric disorders. This can occur by allowing neurotoxins to affect the brain, damaging neuroendocrine tissue, or damaging tissues in the brain at locations such as the receptor sites. Some antidepressants have been thought to have antiviral effects. Symptoms of diseases such as depression may occur after an occurrence of serious infection, and prenatal exposure to infectious organisms has been associated with the development of schizophrenia. Stress and conditioning have specific effects on the suppression of immune function (Liu & Tang, 2018; Vidal

& Pacheco, 2020).

Normal functioning of the endocrine system is often disturbed in people with psychiatric disorders. For example, thyroid functioning is often low in those with bipolar disorder, and people with schizophrenia have a higher incidence of diabetes (see [Unit VI](#)). The hypothalamus sends and receives information through the pituitary, which then communicates with structures in the peripheral aspects of the body. [Figure 8.15](#) presents an example of the communication of the anterior pituitary with a number of organs and structures.

Axes, the structures within which the neurohormones are providing messages, are the most often studied aspect of the neuroendocrine system. These axes always involve a feedback mechanism. For example, the **hypothalamus–pituitary–thyroid axis (HPA)** regulates the release of thyroid hormone by the thyroid gland using thyrotropin-releasing hormone from the hypothalamus to the pituitary and thyroid-stimulating hormone (TSH) from the pituitary to the thyroid. [Figure 8.16](#) illustrates the HPA. The hypothalamic–pituitary–gonadal axis regulates estrogen and testosterone secretion through luteinizing hormone and follicle-stimulating hormone. Interest in the endocrine system is heightened by various endocrine disorders that produce psychiatric symptoms. Addison disease (hypoadrenalism) produces depression, apathy, fatigue, and occasionally psychosis. Hypothyroidism produces depression and some anxiety. Administration of steroids can cause depression, hypomania, irritability, and in some cases, psychosis. Some psychiatric disorders have been associated with endocrine system dysfunction. For example, some individuals with mood disorders show evidence of dysregulation in adrenal, thyroid, and growth hormone axes (see Chapter 26).

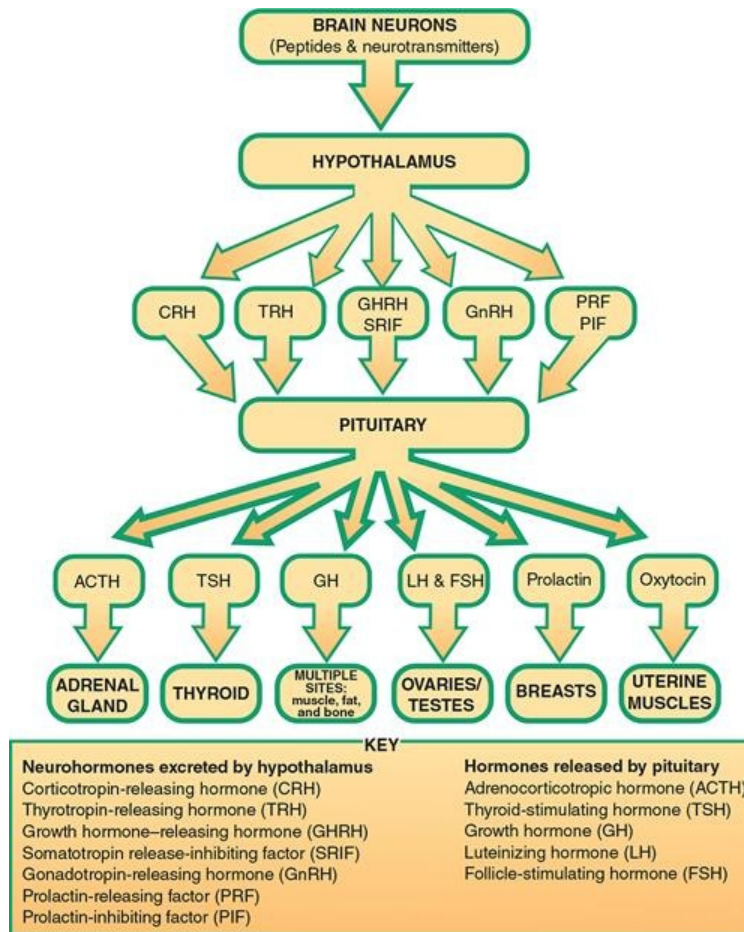

FIGURE 8.15 Hypothalamic and pituitary communication system. The neurohormonal communication system between the hypothalamus and the pituitary exerts effects on many organs and systems.

FIGURE 8.16 Hypothalamic–pituitary–thyroid axis. This figure shows the regulation of thyroid-stimulating hormone (or thyrotropin) secretion by the anterior pituitary. Also depicted are the positive effects of thyrotropin-releasing hormone from the hypothalamus and negative effects of circulating triiodothyronine (T₃) and T₃ from intrapituitary conversion of thyroxine (T₄).
Note. TRH = thyrotropin-releasing hormone; TSH = thyroid-stimulating hormone.

Gut–Brain Axis

The **gut–brain axis** is the term used to define the relationship among the CNS, neuroendocrine and neuroimmune systems including the HPA, sympathetic and autonomic nervous systems, the **enteric nervous system (ENS)**, the vagus nerve, and the gut microbiota. The ENS or “second brain” is a mesh-like system of neurons 104that governs the function of the gastrointestinal system. The ENS can operate independently and communicates with the CNS through the parasympathetic (vagus nerve) and sympathetic (prevertebral ganglia) nervous

system (Li & Owyang, 2003).

The **gut microbiota** is the complex bacterial community located in the gastrointestinal tract (Strandwitz, 2018). Recent research shows that gut microbiota not only is essential for maintaining metabolic and immune health but also influences brain development and neurogenesis and interacts with the ENS and CNS. There is evidence that the gut microbiota has a role in depression, anxiety, Alzheimer disease, and autism spectrum disorder (Bostanciklioglu, 2019; Foster & Neufeld, 2013). It appears that bacteria can respond to and produce neurotransmitters such as the dopamine, norepinephrine, serotonin, and GABA (Strandwitz, 2018).

Chronobiology

Chronobiology involves the study and measure of time structures or biologic rhythms. Some rhythms have a **circadian cycle**, or 24-hour cycle, but others, such as the menstrual cycle, operate in different periods. Rhythms exist in the human body to control endocrine secretions, sleep–wake, body temperature, neurotransmitter synthesis, and more. These cycles may become deregulated and may begin earlier than usual, known as a phase advance, or later than usual, known as a phase delay.

Zeitgebers are specific events that function as time givers or synchronizers and that set biologic rhythms. Light is the most common example of an external zeitgeber. The suprachiasmatic nucleus of the hypothalamus is an example of an internal zeitgeber. Some theorists think that psychiatric disorders may result from one or more biologic rhythm dysfunctions. For example, depression may be, in part, a phase advance disorder, including early morning awakening and decreased time of onset of REM sleep. Seasonal affective disorder may be the result of shortened exposure to light during the winter months. Exposure to specific artificial light often relieves symptoms of fatigue, overeating, hypersomnia, and depression (see [Chapters 12, 26, and 34.](#)).

DIAGNOSTIC APPROACHES

Although no commonly used laboratory tests exist that directly confirm a mental disorder, they are still used as part of the diagnosis of these illnesses. **Biologic**

markers are diagnostic test findings that occur only in the presence of the psychiatric disorder and include such findings as laboratory and other diagnostic test results and neuropathologic changes noticeable in assessment. These markers increase diagnostic certainty and reliability and may have predictive value, allowing for the possibility of preventive interventions to forestall or avoid the onset of illness. In addition, biologic markers could assist in developing evidence-based care practices. If markers are used reliably, it is much easier to identify the most effective treatments and to determine the expected prognoses for given conditions. The psychiatric–mental health nurse should be aware of the most current information on biologic markers so that information, limitations, and results can be discussed knowledgeably with the patient.

Laboratory Tests

For many years, laboratory tests have attempted to measure levels of neurotransmitters and other CNS substances in the bloodstream. Many of the metabolites of neurotransmitters can be found in the urine and cerebrospinal fluid as well. However, these measures have had only limited utility in elucidating what is happening in the brain. Levels of neurotransmitters and metabolites in the bloodstream or urine do not necessarily equate with levels in the CNS. In addition, availability of the neurotransmitter or metabolite does not predict the availability of the neurotransmitter in the synapse, where it must act, or directly relate to the receptor sensitivity. Nonetheless, numerous research studies have focused on changes in neurotransmitters and metabolites in blood, urine, and cerebrospinal fluid. These studies have provided clues but remain without conclusive predictive value and therefore are not routinely used.

Another laboratory approach to the study of some of the psychiatric disorders is the challenge test. A challenge test has been most often used in the study of panic disorders. These tests are usually conducted by intravenously administering a chemical known to produce a specific set of psychiatric symptoms. For example, lactate or caffeine may be used to induce the symptoms of panic in a person who has panic disorder. The biologic response of the individual is then monitored.

Beyond their role in helping to diagnose mental disorders, laboratory tests are also an active part of the normal care and assessment of patients with psychiatric disorders. Many physical conditions mimic the symptoms of mental illness, and

many of the medications used to treat psychiatric illness can produce health problems. For these reasons, the routine care of patients with psychiatric disorders includes the use of laboratory tests such as complete blood counts, thyroid studies, electrolytes, hepatic enzymes, and other evaluative tests. Psychiatric–mental health nurses need to be familiar with these procedures and assist patients in understanding the use and implications of such tests.

Neurophysiologic Procedures

Several neurophysiologic procedures are used in mental health for diagnostic purposes.

105Electroencephalography

Electroencephalography (EEG) is a tried and true method for investigating what is happening inside the living brain. Developed in the 1920s, EEG measures electrical activity in the uppermost nerve layers of the cortex. Usually, 16 electrodes are placed on the patient's scalp. The EEG machine, equipped with graph paper and recording pens, is turned on, and the pens then trace the electrical impulses generated over each electrode. Until the use of computed tomography (CT) in the 1970s, the EEG was the only method for identifying brain abnormalities. It remains the simplest and most noninvasive method for identifying some disorders. It is increasingly being used to identify individual neuronal differences.

An EEG may be used in psychiatry to differentiate possible causes of the patient's symptoms. For example, some types of seizure disorders, such as temporal lobe epilepsy, head injuries, or tumors, may present with predominantly psychiatric symptoms. In addition, metabolic dysfunction, delirium, dementia, altered levels of consciousness, hallucinations, and dissociative states may require EEG evaluation.

Spikes and wave-pattern changes are indications of brain abnormalities. Spikes may be the focal point from which a seizure occurs. However, abnormal activity often is not discovered on a routine EEG while the individual is awake. For this reason, additional methods are sometimes used. Nasopharyngeal leads may be used to get physically closer to the limbic regions. The patient may be

exposed to a flashing strobe light while the examiner looks for activity that is not in phase with the flashing light or the patient may be asked to hyperventilate for 3 minutes to induce abnormal activity if it exists. Sleep deprivation may also be used. This involves keeping the patient awake throughout the night before the EEG evaluation. The patient may then be drowsy and fall asleep during the procedure. Abnormalities are more likely to occur when the patient is asleep. Sleep may also be induced using medication; however, many medications change the wave patterns on an EEG. For example, the benzodiazepine class of drugs increases the rapid and fast beta activity. Many other prescribed and illicit drugs, such as lithium, which increases theta activity, can cause EEG alterations.

In addition to reassuring, preparing, and educating the patient for the examination, the nurse should carefully assess the history of substance use and report this information to the examiner. If a sleep deprivation EEG is to be done, caffeine or other stimulants that might assist the patient in staying awake should be withheld because they may change the EEG patterns.

Polysomnography

Polysomnography is a special procedure that involves recording the EEG throughout a night of sleep. This test is usually conducted in a sleep laboratory. Other tests are usually performed at the same time, including electrocardiography and electromyography. Blood oxygenation, body movement, body temperature, and other data may be collected as well, especially in research settings. This procedure is usually conducted for evaluating sleep disorders, such as sleep apnea, enuresis, or somnambulism. However, sleep pattern changes are frequently researched in mental disorders as well.

Researchers have found that normal sleep divisions and stages are affected by many factors, including drugs, alcohol, general medical conditions, and psychiatric disorders. For example, REM latency, the length of time it takes an individual to enter the first REM episode, is shortened in depression. Reduced delta sleep is also observed. These findings have been replicated so frequently that some researchers consider them biologic markers for depression.

Concept Mastery Alert

Polysomnography involves recording an EEG throughout a night of sleep. A

sleep deprivation EEG involves keeping a client awake the night before the EEG evaluation.

Structural and Functional Imaging

Neuroimaging of the brain involves **structural imaging**, which visualizes the structure of brain and allows diagnosis of gross intracranial disease and injury, and **functional imaging**, which visualizes processing of information. One of the most well-known examples of structural imaging is magnetic resonance imaging (MRI), which produces two- or three-dimensional images of brain structures without the use of x-rays or radioactive tracers. An MRI creates a magnetic field around the patient's head through which radio waves are sent. A functional MRI (fMRI) that creates functional images relies on the properties of oxygenated and deoxygenated hemoglobin to see images of changes in blood flow. The advantage of fMRI is that it is possible to see how the brain works when different stimuli are presented and problems that exist, such as a stroke. The fMRI has replaced most use of positron emission tomography (PET), which measures blood flow and oxygen and glucose metabolism. The emissions from the injected radioactive tracers are rapidly decayed and limit the monitoring of PET to short tasks.

Neuroimaging has limited clinical use in mental health, but its use is increasing in diagnosis and treatment of some disorders such as Alzheimer disease and traumatic brain injury (Henderson et al., 2020). Neuroimaging has promising potential for unlocking the pathophysiology of several mental disorders. With the introduction of the fMRI, it is now possible to study the circuitry and pinpoint genetic-based predisposing factors. An MRI technique, diffusion tensor imaging, allows for viewing macroscopic changes that occur at the axon level (Tønnesen et al., 2018).

Other Neurophysiologic Methods

Evoked potentials (EPs), also called event-related potentials, use the same basic principles as an EEG. They measure changes in electrical activity of the brain in specific regions as a response to a given stimulus. Electrodes placed on the scalp

measure a large waveform that stands out after the administration of repetitive stimuli, such as a click or flash of light. There are several different types of EPs to be measured, depending on the sensory area affected by the stimulus, the cognitive task required, or the region monitored, any of which can change the length of time until the wave occurrence. EPs are used extensively in psychiatric research. In clinical practice, EPs are used primarily in the assessment of demyelinating disorders, such as multiple sclerosis.

However, brain electrical activity mapping studies, which involve a 20-electrode EEG that generates computerized maps of the brain's electrical activity, have found a slowing of electrical activity in the frontal lobes of individuals who have schizophrenia.

SUMMARY OF KEY POINTS

- Neuroscientists now view behavior and cognitive function as a result of complex interactions within the CNS and its plasticity, or its ability to adapt and change in both structure and function.
- Each hemisphere of the brain is divided into four lobes: the frontal lobe, which controls motor speech function, personality, and working memory—often called the executive functions that govern one's ability to plan and initiate action; the parietal lobe, which controls the sensory functions; the temporal lobe, which contains the primary auditory and olfactory areas; and the occipital lobe, which controls visual integration of information.
- The structures of the limbic system are integrally involved in memory and emotional behavior. Dysfunction of the limbic system has been linked with major mental disorders, including schizophrenia, depression, and anxiety disorders.
- Neurons communicate with each other through synaptic transmission. Neurotransmitters excite or inhibit a response at the receptor sites and have been linked to certain mental disorders. These neurotransmitters include Ach, dopamine, norepinephrine, serotonin, GABA, and glutamate.

- Although no one gene has been found to produce any psychiatric disorder, significant evidence indicates that most psychiatric disorders have a genetic predisposition or susceptibility. For individuals who have such genetic susceptibility, the identification of risk factors is crucial in helping to plan interventions to prevent development of that disorder or to prevent certain behavior patterns, such as aggression or suicide.
- PNI examines the relationship among the immune system; the nervous system; the endocrine system; and thoughts, emotions, and behavior.
- The gut microbiota is not only essential for maintaining metabolic and immune health, but also has a role in depression, anxiety, and other mental disorders. It appears that the bacteria can respond to and produce neurotransmitters.
- Chronobiology focuses on the study and measure of time structures or biologic rhythms occurring in the body and associates dysregulation of these cycles as contributing factors to the development of psychiatric disorders.
- Biologic markers are physical indicators of disturbances within the CNS that differentiate one disease process from another, such as biochemical changes or neuropathologic changes. These biologic markers can be measured by several methods of testing, including challenge tests, EEG, polysomnography, EPs, CT scanning, MRI, PET, and single-photon emission CT; the psychiatric nurse must be familiar with all of these methods.

CRITICAL THINKING CHALLENGES

1. A woman who has experienced a “ministroke” continues to regain lost cognitive function months after the stroke. Her husband takes this as evidence that she never had a stroke. How would you approach patient teaching and counseling for this couple to help them understand this occurrence if the stroke did damage to her brain?
2. Your patient has “impaired executive functioning.” Consider what would be a

reasonable follow-up schedule for this patient for counseling sessions. Would it be reasonable to schedule visits at 1 p.m. weekly? Is the patient able to keep to this schedule? Why or why not? What would be the best schedule?

3. Mr. S is unable to sleep after watching an upsetting documentary. Identify the neurotransmitter activity that may be interfering with sleep. (Hint: fight or flight.)
4. 107 Describe what behavioral symptoms or problems may be present in a patient with dysfunction of the following brain area:
 - a. Basal ganglia
 - b. Hippocampus
 - c. Limbic system
 - d. Thalamus
 - e. Hypothalamus
 - f. Frontal lobe
5. Compare and contrast the functions of the sympathetic and parasympathetic nervous systems.
6. Discuss the steps in synaptic transmission, beginning with the action potential and ending with how the neurotransmitter no longer communicates its message to the receiving neuron.
7. Examine how a receptor's usual response to a neurotransmitter might change.
8. Compare the roles of dopamine and Ach in the CNS.
9. Explain how dopamine, norepinephrine, and serotonin all contribute to endocrine system regulation. Suggest some other transmitters that may affect endocrine function.
10. Discuss how the fields of PNI and chronobiology overlap.
11. Compare the methods used to find biologic markers of psychiatric disorders reviewed in this chapter. Consider the potential risks and benefits to the patient.

9

Recovery Framework for Mental Health Nursing

Mary Ann Boyd

KEYCONCEPTS

- advocacy
- peer support specialists
- person-centered care
- psychoeducation
- recovery-oriented nursing care
- shared decision-making

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Identify major concepts underlying the recovery framework.
2. Identify the barriers to recover from mental health problems.
3. Discuss the factors that contribute to a recovery-oriented environment.

KEY TERMS

- Empowerment
- Engagement
- Informed choice model
- Paternalistic model
- Positive mental health
- Shared decision-making model
- Social inclusion
- Stigma resilience

INTRODUCTION

The practice of psychiatric–mental health nursing incorporates the whole person, not only active symptoms and treatment.

KEYCONCEPT **Recovery-oriented nursing care** is a holistic approach characterized by collaborating with persons with mental health problems and disorders to improve health and wellness, live a self-directed life, and strive to meet their full potential.

The overall goal of nursing care is to facilitate a person’s recovery. [Chapter 1](#) discussed the concept of recovery and delineated the principles of recovery. This chapter explores recovery concepts, identifies barriers, and covers approaches that promote recovery.

MENTAL HEALTH RECOVERY

Recovering from mental health disorders is not a new concept. In 1830, John Perceval, son of one of England prime ministers, wrote of his personal recovery from schizophrenia despite the psychiatric treatment he received (Bateson, 1974). In the United States, the recovery model was initially applied only to the care of persons with substance abuse problems. Recently, the recovery model application was expanded to all persons with mental health problems. This change grew out of the consumer/survivor/ex-patient movement following the civil rights movement in the late 1960s. Today, recovery concepts and principles are embraced worldwide in the care and treatment of persons with mental disorders.

Recovery involves achieving a balance between clinical and personal recovery. There are often differing views of mental health recovery between the person with mental health issues and the clinician. The person is often more focused on developing meaning in life and transforming an illness identity to a healthy one, whereas the clinician may want to focus on reduction of symptoms, a return to pre-illness states, and a reduction or cessation of medication (Jacob et al., 2017). It is important that clinicians understand that the therapeutic relationship is collaborative and involves much more than symptom reduction. Building upon trust, the clinician acknowledges the negative impact of mental illness on self-esteem, builds a supportive relationship, listens to personal viewpoints, conveys the belief that recovery is possible, recognizes the person's capacity for recovery, and promotes access to resources.

Positive Mental Health

An emerging concept that is useful in collaborating with a person with mental health issues is **positive mental health**, experiencing more desirable health-related quality of life events than undesirable ones (Sirgy, 2019). Positive mental health can be viewed from a biologic perspective. For example, increasing serotonin and dopamine activity is associated with positive moods. It can also be viewed from a psychosocial view such as spending more time in social activities than in social isolation.

Positive mental health includes satisfying experiences with family, friends, and work. Feelings of well-being are important. Well-being comprises overall life satisfaction, as well as cognitive, emotional, social, and moral growth and development. Self-acceptance, personal growth, purpose in life, autonomy, and

positive relations with others contribute to a positive mental health (Sirgy, 2019).

Person-Centered Care

One of the key concepts in recovery-oriented care is person-centered care. The person is at the center of care—that is, the person is actively involved in determining the best options for their health care circumstances and no longer passively receives a prescription for treatment of a disease. For a person to participate in their care and make meaningful decisions, the individual must be educated about the disorder and treatment options and use collaboration skills to interact with the clinician.

KEYCONCEPT **Person-centered care** is an approach to health care that is organized around health needs and expectations, rather than diseases. The person, family, and community participate in and benefit from a trusted health care system (World Health Organization [WHO], 2015).

In person-centered care, the person is actively engaged in planning interventions based upon individual strengths and needs. The plan, which reflects the person's preferences and values, provides the structure in which the individual, in partnership with the clinician, can identify long- and short-term life goals and skills (Hamovitch et al., 2018). The person–clinician partnership plans and manages mental health and health care issues, provides an opportunity for collaborative and creative thinking, and serves as a tool for gauging progress toward goals (Hamovitch et al., 2018). Research on this approach shows improved engagement in health care and medication adherence (Stanhope et al., 2013).

Person-centered care in nursing practice is built on a strong nurse–patient relationship. A solid therapeutic relationship can help reduce symptom severity and improve global function, community living skills, quality of life, and patient satisfaction with treatment (Kidd et al., 2017). The therapeutic relationship and the person-centered care planning process are linked to each other, each influencing the other. A sense of connection based on caring, support, and continuity enables the person to engage in behavior change needed to improve health and well-being (Hamovitch et al., 2018).

Empowerment

A related concept is **empowerment**, the process of supporting people and communities to take control of their own health needs with the goal of healthy behaviors, positive mental health, self-management of illnesses, and well-being (Grealish et al., 2017; WHO, 2015). Empowerment facilitates patient independence, self-management, and self-efficacy.

Empowerment can lead to better decision-making and foster permanent changes in health. For a person to feel empowered, the individual must have the knowledge and skill to manage a particular issue. By sharing health and mental health care information with patients, they will be able to develop self-management skills. Empowerment and hope are enhanced through patient self-management.

Engagement

Engaging a person in mental health care is the first step in supporting recovery. The interaction between a clinician and a person seeking help can set the tone and course of treatment. The first interaction can start the recovery journey, or it can leave the person feeling hopeless and unwilling to return. Many people who seek mental health care drop out after their first or second visit. Engagement in treatment begins with a trusting and respectful relationships with providers (National Alliance on Mental Illness [NAMI], 2016).

Engagement is the strengths-based process through which individuals with mental health conditions form a healing connection with people that support their recovery and wellness within the context of family, culture, and community (NAMI, 2016). Engagement is not adherence or compliance but a broader concept involving active participation from people who are seeking care and those who deliver care. Lack of effective engagement can result in serious consequences such as hospitalization, homelessness, or even death.

Stigma and discrimination can prevent individuals from seeking help or engaging in a therapeutic relationship. Hospital policies and procedures requiring removal of personal items, locked doors, and sterile environments can magnify feelings of dehumanization and self-stigma. Preventing or treating self-stigma may be important in promoting active engagement in some persons

(Hack et al., 2020).

Shared Decision-Making

The **shared decision-making model** is central in the recovery model; in this approach, the individual is an active participant, and decision-making is shared (Alguera-Lara et al., 2017). In this model, clinician–patient communication and decision-making differ from the following two types of models: a **paternalistic model**, in which the decisions are made by only the clinician and given to the patient, and the **informed choice model**, in which information is given to the patient and the patient makes the decision. (See [Figure 9.1](#) for the continuum of decision-making.) Because patients almost always view psychiatric hospitalization and treatment as unwanted, many people believe that having a mental disorder means a lifelong process of losing power and control over their lives, particularly if their treatment is not voluntary. In the paternalistic model, individuals can feel coerced into treatment and believe they have lost their ability to make decisions. However, empowering the patient to make the decision, as in the informed choice model, excludes clinician expertise and support, which may lead to poor choices.

KEYCONCEPT Shared decision-making helps people make decisions about their care and treatment based on facts and recommendations provided by the clinician. It changes the power imbalance, where the clinician makes the decision, to shared decisions based on relevant information. Shared decision-making is *how* a decision is made, not *what* the final decision is.

FIGURE 9.1 Continuum of decision-making.

The advantages of shared decision-making are reduced symptoms, improved self-esteem, increased service satisfaction, and improved treatment compliance. Other positive outcomes include improved patient knowledge, increased confidence in decision-making, and more active patient involvement (Alguera-Lara et al., 2017).

RECOVERY INTERVENTIONS

The ultimate aim of every intervention is recovery. Along the way, there are important interventions that focus on treating underlying illnesses that places the person in the best position to continue the recovery journey. Effective interventions are based on the person's needs, preparedness to engage, and stage of recovery. Successful outcomes of these interventions lead to engagement of other evidence-based strategies that support the journey (Sly et al., 2020; Winsper et al., 2020).

Psychoeducation

KEYCONCEPT Psychoeducation (PE) is an individual, family, group, or community education intervention with systematic, structured, and didactic teaching–learning interaction that focuses on enhancing knowledge and skills related to a mental health and wellness through emotional support and motivation to enable person to recover from mental health problems and disorders and lead meaningful, productive lives.

Psychoeducation is not a new idea in mental health care with its beginnings in the early 20th century and the de-institutional movement of the 1950s and 1960s (see [Chapter 1](#)). As psychoeducation developed, it became recognized as a useful and effective approach in helping persons with mental health problems actively participate in treatment. Psychoeducation combines cognitive behavioral, educational, and motivational approaches with the goal of providing the person and family with knowledge about the disorder and treatment, and the skills to participate in treatment decisions. Essential elements of psychoeducation include briefing the person about the disorder, problem-solving training, communication techniques, and self-assertiveness (Sarkhel et al., 2020). Psychoeducation is conducted by several mental health disciplines, including nurses, psychiatrists, social workers, psychologists, peer support specialists, and others. Not only does psychoeducation provide knowledge and competence about the disorder, it also promotes insight into the disorders, promotes relapse prevention, and provides skills for crisis management and suicide prevention.

Social Inclusion

Social inclusion, receiving social support and participation in a family and community, is important in successful recovery. Social inclusion is multidimensional with interrelated dimensions including employment or education, housing and neighborhood, and participation in social activities (Filia et al., 2018).

Employment and Education

Employment is one of the most important factors that impacts mental health recovery. Employment gives individuals a sense of purpose and a reason to get up in the morning. Mental health problems, including functional impairment and psychosocial disability, frequently interfere with the ability to work, resulting in absences, interpersonal conflicts, and poor work performance. Symptoms of the illness, side effects of medications, stigma, poor social support, academic underachievement, and poor workplace environment are factors that contribute to difficulty in obtaining and maintaining employment. Individuals who quit work or are fired often find that it is difficult to regain employment. Even when their symptoms are treated, they still may not be hired (Isaacs et al., 2019).

Lack of educational opportunities can lead to lack of skills or qualifications required for employment. Unrecognized learning disabilities can lead to mental health problems that culminate in dropping out of school prior to high school completion (Aro et al., 2019). Education and employment are important goals for persons with mental illness. Employment improves mental health and reduces the overall cost of mental health care (Gibbons& Salkever, 2019). Recovery-oriented care recognizes employment potential and provides social support for gaining meaningful employment. Factors that facilitate obtaining and maintaining employment include personal strengths, social support, accommodative work environment, disclosure, and support from mental health professionals and services (Thomas et al., 2019b).

Housing and Neighborhood

Housing is critical to recovery from mental and substance abuse disorders. Recovery-oriented care promotes safe, affordable, and permanent support housing in the community, with access to benefits and services for individuals, families, and communities. In some instances, housing is sought after the mental disorder is treated and is in remission. In other instances, securing housing is a necessary first step to set the stage for strengthening coping skills and addressing the mental disorder (see Chapter 41).

Housing is more than a place to live. Housing within a safe neighborhood with low crime rates, grocery stores, and access to transportation is critical for a recovery. There should be opportunities to develop social relationships within the neighborhood environment.

Social Activities

The opportunity to engage in social activities results in several positive outcomes. The person is not alone in a room or apartment and can interact and connect with others. Social activities provide opportunities for the person to grow and develop as a member of society. Within the context of social activities, social support from others can emerge (Filia et al., 2019).

Peer Support

Peer support is an integral component of the recovery model.

KEYCONCEPT **Peer support specialists** are people who have been successful in their recovery who help others experiencing similar situations. These specialists are trained and certified to use their experiences to help others and work with the other mental health disciplines in recovery-oriented care. They have well-defined competencies (see [Box 9.1](#)).

Peer support specialists form voluntary relationships with patients on the basis of mutual fit. Peer support specialists engage in a wide range of activities, including advocacy, linkage to resources, sharing of experiences, community and relationship building, group facilitation, skill building mentoring, and goal setting. They also may plan and develop groups, services, or activities, provide training, and administer programs. Because they are able to describe their mental health experiences and can explain their journey of recovery, they are especially

well suited to educate the public and policymakers and can challenge negative stereotypes. Patients have the option to decline services of a peer support specialist (Chinman et al., 2019).

BOX 9.1

Core Competencies for Peer Workers in Behavior Health Services

1. Engages peers in collaborative and caring relationships
2. Provides support
3. Shares lived experiences of recovery
4. Personalizes peer support
5. Supports recovery planning
6. Links to resources, services, and supports
7. Provides information about skills related to health, wellness, and recovery
8. Helps peers to manage crises
9. Values communication
10. Supports collaboration and teamwork
11. Promotes leadership and advocacy
12. Promotes growth and development

Reprinted from Substance Abuse and Mental Health Services Administration. (2015). Core competencies for peer workers in behavioral health services.

https://www.samhsa.gov/sites/default/files/programs_campaigns/brss_tacs/core-competencies_508_12_13_18.pdf

Research supports the effectiveness of peer support specialists in a variety of settings, including urban and rural areas (Castellanos et al., 2018). For example, the Veterans Administration is using certified peer support specialists in remote, community-based clinics to support trauma-affected veterans in a group setting. The veterans are able to share their experiences involving service-related trauma and interpersonal violence in a supportive environment with other veterans and a peer specialist. In this setting, skills are taught to defuse violent thoughts and to prevent further violence (Azevedo et al., 2020).

BARRIERS TO RECOVERY

Poverty

A major barrier in accessing recovery-oriented care is poverty. Individuals with

schizophrenia are more likely than the general population to experience poverty and homelessness (see Chapter 41). Poverty is associated with mental disorders such as depression (Jokela et al., 2019) and schizophrenia (Thomas et al., 2019a).

The lack of monetary resources is the primary definition of what it means to be poor (Sylvestre et al., 2018). Without economic resources such as an income or savings, people are unable to fully participate in society. Individuals and families who meet a certain income threshold are eligible for government supplement, which is minimal and cannot meet basic needs. People with a disability such as a mental illness may qualify for additional support through Social Security Disability Insurance. Their ability to survive on this income will depend on the availability of other resources, such as support from family, friends, and neighbors, available social services, and cost of living (which varies depending on where people live).

Poverty can result in lack of permanent housing, no transportation, and inability to pay for services. Access to health care in the United States is highly dependent on employment; many people with mental health problem are unemployed, resulting in lack of income and health insurance. People with mental illnesses are frequently reliant on public health care, but they may not be able to access services. Public mental health care often involves long wait times for appointments at inconvenient hours. Medications may not be affordable, and even if individuals are able to obtain them, they may have no place to store them. Interpersonal aspects of health care also play a role in people seeking mental health care. Individuals may perceive that they cannot talk to their provider or that their provider does not care about them (Bellamy et al., 2016).

Homelessness

Homelessness is a lack of a fixed, regular, and adequate nighttime residence, and it can be considered as either sheltered or unsheltered. The homeless shelters provide temporary or transitional housing operated by public and private agencies for individuals and families who have no stable housing, including a hotel or motel paid for by government or charitable organization. The unsheltered homeless live in the places that are not ordinarily used for housing such as cars, parks, abandoned building, tents, and bus/train stations (National Alliance to End Homelessness, 2020).

Homelessness is stressful and coping with homelessness is challenging. Substance abuse can be an issue, and people who are homeless are often victims of crime. The incidence of posttraumatic stress disorder among individuals who are homeless may be higher than in the general population. Homeless women are especially in danger of being assaulted, abused, and raped. Individuals with mental illnesses who are homeless are trying to survive and fear being hospitalized or “locked up.” See Chapter 41.

Stigma

Anti-stigma approaches have had the positive impact of reducing public stigma for persons with mental illness (Corrigan & Nieweglowski, 2019) (see [Chapter 2](#)). Self-stigma is a barrier to recovery because individuals internalize the community’s negative views of persons with mental disorders. Self-stigma is associated with increased severity of symptoms of mental disorders. The challenge for nurses and other clinicians is to support **stigma resilience**, a personal trait that means the patient has the capacity to withstand or recover from significant challenges that threaten stability, viability, or development (Hofer et al., 2019).

Lack of Services

Mental health services vary from state to state. Factors that contribute to whether persons with mental health disorders can be treated include access to insurance, access to treatment, quality and cost of insurance, access to special education, and workforce availability. In the United States, 10.3% of adults with mental illness are uninsured, limiting access to services. The number of uninsured declined under the Affordable Care Act, but this law is being challenged, and the number of uninsured is expected to increase if the law is determined to be unconstitutional. The state prevalence of uninsured adults with mental illness ranges from 2.4% in Massachusetts to 22.9% in Wyoming (Mental Health America [MHA], 2020).

More than 57% of adults with a mental health disorder receive no treatment in the United States (ranging from 40.7% in Vermont to 64.8% in California [MHA, 2020]). One out of five adults with a mental illness report inability to

receive needed services. There are several reasons for lack of treatment, including no insurance or limited coverage of services; shortage of psychiatrists, nurses, and other mental health professionals; and lack of treatment services such as inpatient treatment, individual therapy, and community services. Additionally, there is a disconnect between primary care systems and mental health systems (MHA, 2020).

Services for children and youth are even more sparse. Only 28.2% of youth with severe depression receive some consistent treatment (7–25 visits per year). These services vary by state, with 53.9% of youth with severe depression in Maryland receiving some outpatient treatment compared to 13.5% in South Carolina (MHA, 2020).

Access to mental health care is very limited in rural areas. Health care providers are concentrated in urban areas, leaving rural counties without an adequate number of health care professionals. It is estimated that 1,600 counties in the United States do not have an accredited mental health provider. Farmers and their families need mental health support and treatment; stress among farm families is high, and they need to know how to manage the stress effectively. The National Health Service Corps and telemedicine are providing some help to the rural communities (National Association for Rural Mental Health [NARMH], 2020).

SOCIETAL ROLE IN PROMOTING A RECOVERY-ORIENTED ENVIRONMENT

Advocacy

The World Health Organization recognized the need for mental health advocacy to promote the human rights of persons with mental disorders and to reduce stigma and discrimination in a 2003 publication, *Advocacy for Mental Health* (WHO, 2003).

KEYCONCEPT **Advocacy** is various actions aimed at changing the major structural and attitudinal barriers to achieving positive mental health outcomes. It is an important means of raising awareness of mental health issues.

Mental health advocacy began when families of people with mental disorders

made their voices heard and raised awareness of the needs and mistreatment of their loved ones. Individuals with the disorders joined their families to develop advocacy organizations to influence legislation and policy development. Today, many mental health workers and their organizations have joined the movement to advocate for the mental health needs, rights, and recovery of the general population.

The concept of advocacy includes several elements such as awareness raising; providing information, education, training, and counseling; and mutual help, mediating, defending, and denouncing. Through the advocacy movement, society's negative perception of persons with mental disorders is being challenged and gradually replaced with more realistic, empathic perceptions.

Advocacy occurs at many levels. Individuals with mental disorders advocate for their own recovery. They are often motivated to contact advocacy groups in the hope that advocates will intervene on their behalf through effective communication with health care providers (Morrison et al., 2018). They may contact the local advocacy service in their facility or a local community advocacy group such as National Alliance on Mental Illness or Mental Health America.

Advocacy groups and organizations play important roles promoting national and international agendas. These groups develop databases with patient groups, families, and organizations. Establishing a regular flow of information with governmental decision-making groups and other organizations, they are instrumental in formulating and evaluating policy, plans, programs, legislation, and quality improvement standards. Other activities include establishing educational initiatives, conducting media activities, and organizing public events to raise awareness of mental health issues.

Removing Social, Economic, and Political Barriers

An important step in promoting a recovery-oriented environment is the reduction of stigma and stigmatizing messages. Education about mental health disorders and treatment is critical in reducing discrimination of persons with mental disorders. National media organizations should use nonstigmatizing language in their publications.

Universal access to mental health services would help reduce the disparities between those who are insured and those who are not. More national mental

health programs such as the National Suicide Hotline, a 24-hour crisis intervention hotline offering counseling and referral, would also be helpful.

Health care workers can play an important role in advocating for quality mental health care through participating in activities of patient and family groups. They can educate communities and support access to services.

RECOVERY-ORIENTED PSYCHIATRIC–MENTAL HEALTH NURSING PRACTICE

Recovery-oriented care is integral to the practice of psychiatric–mental health nursing and consistent with relationship-based care (American Nurses Association [ANA], American Psychiatric Nursing Association [APNA], International society of Psychiatric-Mental Health Nurses [ISPN], 2014). Psychiatric–mental health nurses develop partnerships with patients through therapeutic relationships. Psychiatric–mental health nursing approaches are based on shared decision-making. Interventions are determined by both the nurse and the patient.

As the care paradigm has shifted from nurse-directed care to recovery-oriented care with shared decision-making, nurses have the opportunity to truly practice from a holistic perspective. Also, nurses are now able to engage peer support specialists in supporting patients through recovery.

SUMMARY OF KEY POINTS

- Mental health recovery is based on concepts of person-centered care, empowerment, shared decision-making, employment, housing, and peer support.
- Empowering the patient to engage in the care process requires that the individual is educated on health and mental health issues and approaches. The person must have the knowledge and skills to engage in a meaningful collaborative process.
- Person-centered care places the person in the center of the care process. The

individual becomes a partner to the clinician and together they decide the best approach based on persons circumstances. The care approach is individualized; one person's care plan will look different from another.

- In shared decision-making, the patient is an active participant in the decision. The advantages of shared decision-making include reduced symptoms, improved self-esteem, increased service satisfaction, and improved treatment compliance.
- Employment is a goal of recovery. In some instances, supportive employment will be needed to accommodate disabilities.
- Housing is critical to recovery. There are several types of housing arrangements such as independent, transitional, and supportive.
- Peer support is an integral component of recovery. Peer support specialists are new members of the mental health team who are recovering from mental health problems. These individuals use their experiences to help others.
- Barriers to recovery include poverty, homelessness, stigma, and lack of services. Advocacy plays an important role in promoting a recovery-oriented environment and seeks to remove social, economic, and political barriers.
- Recovery-oriented psychiatric–mental health nursing practice is based on developing partnerships with patients through the use of the therapeutic relationship.

CRITICAL THINKING CHALLENGES

1. Compare a traditional medical approach to care with recovery-oriented care.
2. Using the nursing process, describe the inclusion of the person-centered approach.
3. Compare and contrast the paternalistic, informed-choice, and shared decision-making approaches for a patient who has schizophrenia and can be treated with an oral or long-acting injectable.
4. Discuss with a patient how mental health issues impact employment and housing.

- i. What factors might interfere with the ability of the person who is mentally ill to participate in treatment?
- j. What barriers to communication might the nurse experience when relating to the person who is homeless and mentally ill?

Movie Viewing Guides

Home: (2013). Jack (Gbenga Akinnagbe) lives in a group home and is suffering from a mental illness. He wants to have his own home and reconnect with his son. When he moves into an apartment, he finds that living alone is more difficult than he expected.

VIEWING POINTS: How does Jack's illness affect his ability to maintain his independence? What does having his own home represent to Jack?

UNIT III:

Contemporary Psychiatric Nursing Practice

10

Communication and the Therapeutic
Relationship

Cheryl Forchuk and Rebecca Luebbert

KEYCONCEPTS

- nurse–patient relationship
- self-awareness
- therapeutic communication

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Identify the importance of self-awareness in nursing practice.
2. Demonstrate the appropriate use of verbal and nonverbal communication skills.
3. Distinguish between active and passive listening.
4. Incorporate therapeutic communication strategies when working with patients.
5. Identify common barriers to therapeutic communication.
6. Explain how the nurse can establish a therapeutic relationship with patients by using rapport and empathy.
7. Understand the physical, emotional, and social boundaries of the nurse–patient relationship.
8. Appreciate the significance of adaptive and maladaptive defense mechanisms.
9. Explain what occurs in each of the three phases of the nurse–patient relationship: orientation, working, and resolution.
10. Describe what characterizes a nontherapeutic or deteriorating nurse–patient relationship.

KEY TERMS

- Active listening
- Boundaries
- Communication blocks
- Content themes
- Countertransference
- Defense mechanisms
- Deteriorating relationship
- Empathy
- Empathic linkages
- Introspective

- Nontherapeutic relationship
 - Nonverbal communication
 - Orientation phase
 - Passive listening
 - Process recording
 - Rapport
 - Resolution phase
 - Self-disclosure
 - Strength-based communication
 - Symbolism
 - Transference
 - Verbal communication
 - Working phase
-

INTRODUCTION

Patients with psychiatric disorders have special communication needs that require advanced therapeutic communication skills. In psychiatric nursing, the nurse–patient relationship is an important tool used to reach treatment goals. The purpose of this chapter is to help the nurse (1) develop self-awareness and communication techniques needed for a therapeutic nurse–patient relationship, (2) examine the specific stages or steps involved in establishing the relationship, (3) explore the specific factors that make a nurse–patient relationship successful and therapeutic, (4) differentiate therapeutic from nontherapeutic relationships, and (5) recognize the significance and impact of a patient’s use of **defense mechanisms**.

SELF-AWARENESS

Self-awareness is the process of understanding one’s own beliefs, thoughts, motivations, biases, and limitations and recognizing how they affect others. Without self-awareness, nurses will find it impossible to establish and maintain therapeutic relationships with patients. “Know thyself” is a basic tenet of psychiatric–mental health nursing ([Box 10.1](#)).

A well-developed sense of self-awareness can only come after nurses carry out self-examination. Self-awareness requires a willingness to be **introspective** and to examine one's own personal beliefs, attitudes, and motivations. While this process may be uncomfortable and time consuming, this objective examination is an essential exercise for a professional nurse. Self-examination should be an ongoing process and involves reflecting on the personal meaning of the current situation. This reflection can relate to the nurse's past situations and issues related to their own personal values. Self-examination without the benefit of another's perspective might lead to a biased view of self. Therefore, conducting self-examinations with a trusted individual who can give objective, but realistic, feedback is best.

KEYCONCEPTS **Self-awareness** is the process of understanding one's own beliefs, thoughts, motivations, biases, and limitations and recognizing how they affect others.

The Biopsychosocial Self

Each nurse brings a biopsychosocial self to nursing practice. The patient perceives the biologic dimension of the nurse in terms of physical characteristics: age, gender, body weight, height, ethnic or racial background, and any other observed physical characteristics. Additionally, the nurse can have a certain genetic composition, an illness, or an unobservable physical disability that may influence the quality or delivery of nursing care. The nurse's psychological state also influences how they analyze patient information and select treatment interventions. An emotional state or behavior can inadvertently influence the therapeutic relationship. For example, a nurse who has just learned that her child is using illegal drugs and who has a patient with a history of drug use may inadvertently project a judgmental attitude toward her patient, which would interfere with the formation of a therapeutic relationship. The nurse needs to examine underlying emotions, motivations, and beliefs and determine how these factors shape behavior.

BOX 10.1

"Know Thyself"

- What physical problems or illnesses have you experienced?
- What significant traumatic life events (e.g., divorce, death of significant person, abuse, disaster) have you experienced?
- What prejudiced or embarrassing beliefs and attitudes about groups different from yours can you identify from your family, significant others, and yourself?
- Which sociocultural factors in your background could contribute to your being rejected by members of other cultures?
- How would the above experiences affect your ability to care for patients?

The nurse's social biases can be particularly problematic for the nurse–patient relationship. Although the nurse may not verbalize these values to patients, some are readily evident in the nurse's behavior and appearance. A patient may perceive biases in the nurse as a result of how the nurse acts or appears at work. Other sociocultural values may not be immediately obvious to the patient, for example, the nurse's religious or spiritual beliefs or feelings about death, divorce, abortion, or homosexuality. These beliefs and thoughts can influence how the nurse interacts with a patient who is dealing with such issues. Similarly, cultural beliefs and patterns of communicating may influence the emerging relationship by each partner's behaviors conforming to or confronting cultural norms.

Understanding Personal Feelings and Beliefs and Changing Behavior

Nurses must understand their own personal feelings and beliefs and try to avoid projecting them onto patients. The development of self-awareness will enhance the nurse's objectivity and foster a nonjudgmental attitude, which is so important for building and maintaining trust throughout the nurse–patient relationship. Soliciting feedback from colleagues and supervisors about how personal beliefs or thoughts are being projected onto others is a useful self-assessment technique. One of the reasons that ongoing clinical supervision is so important is that the supervisor really knows the nurse and can continually observe for inappropriate communication and question assumptions that the nurse may hold. Clinical supervision is different from administrative supervision in that the focus is on the therapeutic development of the helper and it does not generally involve an administrative or a reporting relationship.

After a nurse has identified and analyzed their personal beliefs and attitudes, behaviors that were driven by prejudicial ideas may change. The change process

requires introspective analysis that may result in viewing the world differently. Through self-awareness and conscious effort, the nurse can change learned behaviors to engage effectively in therapeutic relationships with patients. Nevertheless, sometimes a nurse realizes that some attitudes are too ingrained to support a therapeutic relationship with a patient with different beliefs. In such cases, the nurse should refer the patient to someone with whom the patient is more likely to develop a successful therapeutic relationship.

EFFECTIVE COMMUNICATION

Effective communication, including verbal and nonverbal techniques, is a building block for all successful relationships. The nurse–patient relationship is built on therapeutic communication, the ongoing process of interaction through which meaning emerges ([Box 10.2](#)). **Verbal communication**, which is principally achieved by spoken words, includes the underlying emotion, context, and connotation of what is actually said. **Nonverbal communication** includes gestures, expressions, and body language. Both the patient and the nurse use verbal and nonverbal communication. To respond therapeutically in a nurse–patient relationship, the nurse is responsible for assessing and interpreting all forms of patient communication.

NCLEXNOTE In analyzing patient–nurse communication, nonverbal behaviors and gestures are communicated first. If a patient’s verbal and nonverbal communications are contradictory, priority should be given to the nonverbal behavior and gestures.

Verbal Communication

The process of verbal communication involves a sender, a message, and a receiver. The patient is often the sender, and the nurse is often the receiver, but communication is always two way ([Fig. 10.1](#)). The patient formulates an idea, encodes that message (puts ideas into words), and then transmits the message with emotion. The patient’s words and their underlying emotional tone and connotation communicate the individual’s needs and emotional problems. The nurse receives the message, decodes it (interprets the message, including its feelings, connotation, and context), and then responds to the patient.

BOX 10.2

Principles of Therapeutic Communication

- The patient should be the primary focus of the interaction.
- A professional attitude sets the tone of the therapeutic relationship.
- Use self-disclosure cautiously and only when the disclosure has a therapeutic purpose.
- Avoid social relationships with patients.
- Maintain patient confidentiality.
- Assess the patient's intellectual competence to determine the level of understanding.
- Implement interventions from a theoretic base.
- Maintain a nonjudgmental attitude. Avoid making judgments about the patient's behavior.
- Avoid giving advice. By the time the patient sees the nurse, they have had plenty of advice.
- Guide the patient to reinterpret their experiences rationally.
- Track the patient's verbal interaction through the use of clarifying statements.
- Avoid changing the subject unless the content change is in the patient's best interest.

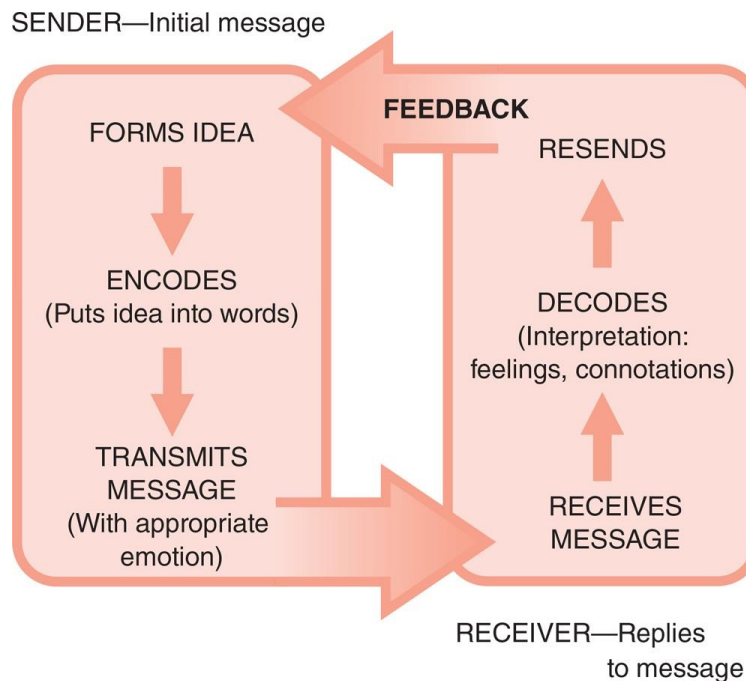

Figure 10.1: The communication process.

(Adapted with permission from Boyd, M. [1995]. Communication with patients, families, healthcare providers, and diverse cultures. In M. K. Strader & P. J. Decker [Eds.]. *Role transition to patient care management* [p. 431]. Appleton & Lange.)

On the surface, this interaction is deceptively simple; unseen complexities lie

beneath. Is the message the nurse receives consistent with the patient's original idea? Did the nurse interpret the message as the patient intended? Is the verbal message consistent with the nonverbal flourishes that accompany it? Validation is essential to ensure that the nurse has received the information accurately.

Nonverbal Communication

Gestures, facial expressions, and body language actually communicate more than verbal messages. Under the best circumstances, body language mirrors or enhances what is verbally communicated. However, if verbal and nonverbal messages conflict, the listener should rely on the nonverbal message. For example, if a patient says that they feel fine but has a sad facial expression and is slumped in a chair away from others, the message of sadness and depression, rather than the patient's report of feeling fine, should be accepted. The same is true of a nurse's behavior. For example, if a nurse tells a patient "I am happy to see you" but the nurse's facial expression communicates indifference, the patient will receive the message that the nurse is bored.

People with psychiatric problems often have difficulty verbally expressing themselves and interpreting the emotions of others. Because of this, nurses need to continually assess the nonverbal communication needs of patients. Eye contact (or lack thereof), posture, movement (shifting in a chair, pacing), facial expressions, and gestures are nonverbal behaviors that communicate thoughts and feelings. For example, a patient who is pacing and restless may be upset or having a reaction to medication. A clenched fist usually indicates that a person feels angry or is hostile.

Nonverbal behavior varies from culture to culture. The nurse must, therefore, be careful to understand their own cultural context as well as that of the patient. For example, in some cultures, it is considered disrespectful to look a person straight in the eye. In other cultures, not looking a person in the eye may be interpreted as "hiding something" or as having low self-esteem. Whether one points with the finger, nose, or eyes and how much hand gesturing to use are other examples of nonverbal communication that may vary considerably among cultures. The nurse needs to be aware of cultural differences in communication in the context of each relationship and may need to consult with a cultural interpreter or use other learning opportunities to ensure that their communication is culturally congruent.

Nurses should use positive body language, such as sitting at the same eye level as the patient with a relaxed posture that projects interest and attention. Leaning slightly forward helps engage the patient. Generally, the nurse should not cross their arms or legs during therapeutic communication because such postures pose a barrier to interaction. Uncrossed arms and legs project openness and a willingness to engage in conversation (Fig. 10.2). Any verbal message should be consistent with nonverbal messages.

Figure 10.2: Open and closed body language.

THERAPEUTIC COMMUNICATION STRATEGIES AND TECHNIQUES

KEYCONCEPTS Therapeutic communication is the ongoing process of interaction through which meaning emerges.

Therapeutic and social interactions are very different. In a therapeutic communication, the nurse focuses on the patient and patient-related issues. Activities should have a definite purpose, and conversation should focus only on the patient. The nurse must not attempt to meet their own social or other needs during the activity.

Limiting Self-Disclosure

One of the most important principles of therapeutic communication for the nurse to follow is to focus the interaction on the patient's concerns. **Self-disclosure**, telling the patient personal information, generally is not a good idea. The conversation should focus on the patient, not the nurse. If a patient asks the nurse personal questions, the nurse should elicit the underlying reason for the request. The nurse can then determine how much personal information to disclose, if any. In revealing personal information, the nurse should be purposeful and have identified therapeutic outcomes. For example, a male patient who was struggling with the implications of marriage and fidelity asked a male nurse if he had ever had an extramarital affair. The nurse interpreted the patient's statement as seeking role-modeling behavior for an adult man and judged self-disclosure in this instance to be therapeutic. He honestly responded that he did not engage in affairs and redirected the discussion back to the patient's concerns.

Nurses sometimes may feel uncomfortable avoiding patients' questions for fear of seeming rude. As a result, they might sometimes disclose too much personal information because they are trying to be "nice." However, being nice is not necessarily therapeutic. As appropriate, redirecting the patient, giving a neutral or vague answer, or saying "Let's talk about you" may be all that is necessary to limit self-disclosure. In some instances, nurses may need to tell the patient directly that the nurse will not share personal information ([Table 10.1](#)).

Active Listening

Listening is an ongoing activity by which the nurse attends to the patient's verbal and nonverbal communication. The art of listening is developed through careful attention to the content and meaning of the patient's speech. There are two types of listening: passive and active. **Passive listening** involves sitting quietly and letting the patient talk. A passive listener allows the patient to ramble and does not focus or guide the thought process. This form of listening does not foster a therapeutic relationship. Body language during passive listening usually communicates boredom or indifference ([Fig. 10.3](#)).

Table 10.1: SELF-DISCLOSURE IN THERAPEUTIC VERSUS SOCIAL RELATIONSHIPS

Situation	Appropriate Therapeutic Response	Inappropriate Social Response with Rationale
A patient asks the nurse if she had fun over the weekend.	“The weekend was fine. How did you spend your weekend?”	“It was great. My boyfriend and I went to dinner and a movie.” <i>(This self-disclosure has no therapeutic purpose. The response focuses the conversation on the nurse, not the patient.)</i>
A patient asks a student nurse if she has ever been to a particular bar.	“Many people go there. I’m wondering if you have ever been there?”	“Oh yes—all the time. It’s a lot of fun.” <i>(Sharing information about outside activities is inappropriate.)</i>
A patient asks a nurse if mental illness is in the nurse’s family.	“Mental illnesses do run in families. I’ve had a lot of experience caring for people with mental illnesses.”	“My sister is being treated for depression.” <i>(This self-disclosure has no purpose, and the nurse is missing the meaning of the question.)</i>
While shopping with a patient, the nurse sees a friend, who approaches them.	To her friend: “I know it looks like I’m not working, but I really am. I’ll see you later.”	“Hi, Bob. This is Jane Doe, a patient.” <i>(Introducing the patient to the friend is very inappropriate and violates patient confidentiality.)</i>

Through **active listening**, the nurse focuses on what the patient is saying, interprets the underlying meaning, and responds to the message objectively. The nurse’s verbal and nonverbal behaviors indicate active listening. The nurse usually responds indirectly using techniques such as open-ended statements, reflection (see [Table 10.2](#)), and questions that elicit additional responses from the patient. In active listening, the nurse should avoid changing the subject and instead follow the patient’s lead. At times, however, it is necessary to direct a patient’s focus on a specific topic or to clarify their thoughts or beliefs about that topic.

Figure 10.3: Negative body language.

NCLEXNOTE Self-disclosure can be used in very specific situations, but self-disclosure is not the first intervention to consider. In prioritizing interventions, active listening is one of the first to use.

Selection of Communication Techniques

Psychiatric nurses use many therapeutic techniques in establishing relationships and helping patients focus on their problems. Asking a question, restating, and reflecting are examples of such techniques. These techniques may at first seem

artificial, but with practice, they can be useful. [Table 10.2](#) lists useful therapeutic techniques along with examples. Choosing the best response begins with assessing and interpreting the meaning of the patient’s communication—both verbal and nonverbal. For example, if a patient is angry and upset, should the nurse invite the patient to sit down and discuss the problem, walk quietly with the patient, or simply observe the patient from a distance and not initiate conversation?

Nurses should not necessarily take verbal messages literally, especially when a patient is upset or angry. For example, one nurse walked into the room of a newly admitted patient, who accused, “You locked me up and threw away the key.” The nurse could have responded defensively that they had nothing to do with the patient being admitted; however, that response could have ended in an argument, and communication would have been blocked. Fortunately, the nurse recognized that the patient was communicating frustration at being in a locked psychiatric unit and did not take the accusation personally.

Table 10.2: VERBAL COMMUNICATION TECHNIQUES

Technique	Definition	Example	Use
Acceptance	Encouraging and receiving information in a nonjudgmental and interested manner	<i>Patient:</i> I have done something terrible. <i>Nurse:</i> I would like to hear about it. It’s OK to discuss it with me.	Used in establishing trust and developing empathy
Confrontation	Presenting the patient with a different reality of the situation	<i>Patient:</i> My doctor won’t talk to me. <i>Nurse:</i> I was in the room yesterday when you refused to	Used cautiously to immediately redefine the patient’s reality. However, if used inappropriately, a nonjudgmental attitude is critical for confrontation to be effective.

Doubt	Expressing or voicing doubt when a patient relates a situation	<p> speak with him. <i>Patient:</i> My best friend hates me. She never calls me. <i>Nurse:</i> From what you have told me, that does not sound like her. When did she call you last? </p>	Used carefully and only when the nurse feels confident about the details. It is used when the nurse wants to guide the patient toward other explanations.
Interpretation	Putting into words what the patient is implying or feeling	<p> <i>Patient:</i> I could not sleep because someone would come into my room and rape me. <i>Nurse:</i> It sounds like you were scared last night. </p>	Used in helping the patient identify underlying thoughts or feelings
Observation	Stating to the patient what the nurse is observing	<p> <i>Nurse:</i> You are trembling and perspiring. When did this start? </p>	Used when a patient's behaviors (verbal or nonverbal) are obvious and unusual for that patient
Open-ended statements	Introducing an idea and letting the patient respond	<p> <i>Nurse:</i> Trust means... </p>	Used when helping the patient explore feelings or

		<i>Patient:</i> gain insight That someone will keep you safe.	
Reflection	Redirecting the idea back to the patient for classification of important emotional overtones, feelings, and experiences; it gives patients permission to have feelings they may not realize they have	<i>Patient:</i> Should I go home for the weekend? <i>Nurse:</i> Should you go home for the weekend?	Used when the patient is asking for the nurse's approval or judgment; use of reflection helps the nurse maintain a nonjudgmental approach
Restatement	Repeating the main idea expressed lets the patient know what was heard	<i>Patient:</i> I hate this place. I don't belong here. <i>Nurse:</i> You don't want to be here.	Used when trying to clarify what the patient has said
Silence	Remaining quiet but nonverbally expressing interest during an interaction	<i>Patient:</i> I am angry! <i>Nurse:</i> (Silence) <i>Patient:</i> My wife had an affair.	Used when the patient needs to express ideas but may not know quite how to do it; with silence, the patient can focus on putting thoughts together
Validation	Clarifying the nurse's understanding of the situation	<i>Nurse:</i> Let me see if I understand.	Used when the nurse is trying to understand a situation the patient is trying to describe

The next step is identifying the desired patient outcome. To do so, the nurse should engage the patient with eye contact and quietly try to interpret the patient's feelings. In this example, the desired outcome was for the patient to clarify the hospitalization experience. The nurse responded, "It must be frustrating to feel locked up." The nurse focused on the patient's feelings rather

than on the accusations, which reflected an understanding of the patient's feelings. The patient knew that the nurse accepted these feelings, which led to further discussion. It may seem impossible to plan reactions for each situation, but with practice, the nurse will begin to respond automatically in a therapeutic way.

Silence

Silence consists of deliberate pauses to encourage the patient to reflect and eventually respond. One of the most difficult but often most effective communication techniques is the use of silence during verbal interactions. By maintaining silence, the nurse allows the patient to gather thoughts and to proceed at their own pace. It is important that the nurse not interrupt periods of silence because of their own anxiety or concern of “not doing anything” if sitting quietly with a patient.

Validation

Another important technique is *validation*, which means explicitly checking one's own thoughts or feelings with another person. To do so, the nurse must own their own thoughts or feelings by using “I” statements (Orlando, 1961). Validation generally refers to observations, thoughts, or feelings and seeks explicit feedback. For example, a nurse who sees a patient pacing the hallway before a planned family visit may conclude that the patient is anxious. Validation may occur with a statement such as, “I notice you pacing the hallway. I wonder if you are feeling anxious about the family visit.” The patient may agree, “Yes. I keep worrying about what is going to happen!” or disagree, “No. I have been trying to get into the bathroom for the last 30 minutes, but my roommate is still in there!”

Strength-Based Communication

Strength-based communication should be supportive, focusing on the patient's

strengths instead of potential deficits. Language that promotes acceptance and respect should be favored over language that distracts from acceptance of the person. For example, instead of stating that a patient is “manipulative,” an alternate consideration is that the person is “resourceful; trying to get help.” An “entitled” person might be viewed instead as someone who is “aware of their rights.” Instead of noting that a patient is “resistant to treatment,” it may be that the person is instead “choosing a different treatment.” The nurse should incorporate language that promotes the strengths and unique characteristic of their patients (Ashcraft & Anthony, 2014).

Avoiding Blocks to Communication

Some verbal techniques block interactions and inhibit therapeutic communication (Table 10.3). One of the biggest blocks to communication is giving advice, particularly when others have already given the same advice. Giving advice is different from supporting a patient through decision-making. The therapeutic dialogue presented in Box 10.3 differentiates between advice (telling the patient what to do or how to act) and therapeutic communication, through which the nurse and patient explore alternative ways of viewing the patient’s world. The patient can then reach their own conclusions about the best approaches to use.

Table 10.3: TECHNIQUES THAT INHIBIT COMMUNICATION

Technique	Definition	Example	Problem
Advice	Telling a patient what to do	<i>Patient:</i> I am struggling at work. <i>Nurse:</i> You should probably find a new job.	The nurse solves the patient’s problem, which implies that the nurse knows best and may not be the appropriate solution; it also encourages dependency on the nurse.
Agreement	Agreeing with a particular	<i>Patient:</i> Abortions are to change their view now that the	The patient is denied the opportunity

	viewpoint of a patient	sinful. <i>Nurse:</i> I agree.	nurse agrees.
Challenges	Disputing the patient's beliefs with arguments, logical thinking, or direct order	<i>Patient:</i> I'm a cowboy. <i>Nurse:</i> If you are a cowboy, what are you doing in the hospital?	The nurse belittles the patient and decreases the patient's self-esteem. The patient will avoid relating to the nurse who challenges.
Reassurance	Telling a patient that everything will be OK	<i>Patient:</i> I don't think I will ever get better. <i>Nurse:</i> Hang in there. Everything will turn out just fine.	The nurse makes a statement that may not be true. The patient is blocked from exploring their feelings.
Disapproval	Judging the patient's situation and behavior	<i>Patient:</i> I'm so sorry. I did not mean to kill my mother. <i>Nurse:</i> You should be. How could anyone kill their mother?	The nurse belittles the patient. The patient will avoid the nurse.

BOX 10.3 • GIVING ADVICE VERSUS RECOMMENDATIONS

Ms. J has just received a diagnosis of phobic disorder and has been given a prescription for fluoxetine (Prozac). She was referred to the home health agency because she does not want to take her medication. She is fearful of becoming suicidal. Two approaches are given in the following section.

INEFFECTIVE COMMUNICATION (ADVICE)

Nurse: Ms. J, the doctor has ordered the medication because it will help with your anxiety.

Ms. J: Yes, but I don't want to take the medication. I'm afraid it will make me suicidal. Some psychiatric medication does that. I haven't had any attacks for 2 weeks, and it seems too risky since I'm doing better.

I'm scared of the side effects.

Nurse: This medication has rarely had that side effect. You should try it and see if you have any suicidal thoughts.

Ms. J: [Remains silent for a while, crosses her legs, and looks away from the nurse and down at her feet] Okay.

(The nurse leaves, and Ms. J decides not to take the medication. Within 1 week, Ms. J is taken to the emergency room with a panic attack.)

EFFECTIVE COMMUNICATION

Nurse: Ms. J, how have you been doing?

Ms. J: So far, so good. I haven't had any attacks for 2 weeks.

Nurse: I understand that the doctor gave you a prescription for medication that may help with the panic attacks.

Ms. J: Yes, but I don't want to take it. I'm afraid of becoming suicidal. Some of this psychiatric medication does that. I don't really want to take a needless risk since I've been feeling better.

Nurse: Those worries are understandable. Have you ever had feelings of hurting yourself?

Ms. J: Not yet.

Nurse: If you took the medication and had thoughts like that, what would you do?

Ms. J: I don't know, that's why I'm scared.

Nurse: I think I see your dilemma. This medication may help with your panic attacks, but if the medication produces suicidal thoughts, then it might compromise your progress and that's a pretty serious risk. Is that correct?

Ms. J: Yeah, that's it.

Nurse: What are the circumstances under which you would feel more comfortable trying the medication?

Ms. J: If I knew that I would not have suicidal thoughts. If I could be assured of that.

Nurse: I can't guarantee that, but perhaps we could create an environment in which you would feel safe. I could call you every few days to see if you are having any of these thoughts and, if so, I could help you deal with them and make sure you see the doctor to review the medication.

Ms. J: Oh, that helps. If you do that, then I think that I will be alright.

(Ms. J successfully takes the medication.)

CRITICAL THINKING CHALLENGE

- Contrast the communication in the first scenario with that in the second.
- What therapeutic communication techniques did the second nurse use that may have contributed to a better outcome?
- Are there any cues in the first scenario that indicate that the patient will not follow the nurse's advice? Explain.

CONSIDERATIONS FOR EFFECTIVE COMMUNICATION AND RELATIONSHIPS

When the nurse is interacting with patients, additional considerations can

enhance the quality of communication. This section describes the importance of **rapport**, **empathy**, recognition of **empathic linkages**, the role of **boundaries** and body space, and recognition of defense mechanisms in nurse–patient interactions.

Rapport

Rapport, interpersonal harmony characterized by understanding and respect, is important in developing a trusting, therapeutic relationship. Nurses establish rapport through interpersonal warmth, a nonjudgmental attitude, and a demonstration of understanding. A skilled nurse will establish rapport that will alleviate the patient’s anxiety in discussing personal problems.

People with psychiatric problems often feel alone and isolated. Establishing rapport helps lessen feelings of being alone. When rapport develops, a patient feels comfortable with the nurse and finds self-disclosure easier. The nurse also feels comfortable and recognizes that an interpersonal bond or alliance is developing. All of these factors—comfort, sense of sharing, and decreased anxiety—are important in establishing and building the nurse–patient relationship.

Empathy

The use of empathy in a therapeutic relationship is central to psychiatric–mental health nursing. Empathy is sometimes confused with sympathy, which is the expression of compassion and kindness. Empathy is the ability to experience, in the present, a situation as another did at some time in the past. It is the ability to put oneself in another person’s circumstances and to imagine what it would be like to share their feelings. The nurse does not actually have to have had the experience but has to be able to imagine the feelings associated with it. For empathy to develop, there must be a giving of self to the other individual and a reciprocal desire to know each other personally. The process involves the nurse receiving information from the patient with open, nonjudgmental acceptance and communicating this understanding of the experience and feelings so that the patient feels understood.

Recognition of Empathic Linkages

While empathy is essential, it is important for the nurse to be aware of empathic linkages, the direct communication of feelings (Peplau, 1952, 1992). This commonly occurs with anxiety. For example, a nurse may be speaking with a patient who is highly anxious, and the nurse may notice their own speech becoming more rapid in tandem with the patient's. The nurse may also become aware of subjective feelings of anxiety. It may be difficult for the nurse to determine if the anxiety was communicated interpersonally or if the nurse is personally reacting to some of the content of what the patient is communicating. However, being aware of one's own feelings and analyzing them are crucial to determining the source of the feeling and addressing associated problems.

Biopsychosocial Boundaries and Body Space Zones

Boundaries are the defining limits of individuals, objects, or relationships. Boundaries mark territory, distinguishing what is “mine” from what is “not mine.” Human beings have many different types of boundaries. Material boundaries, such as fences around property, artificially imposed state lines, and bodies of water, define territory as well as provide security and order. Personal boundaries can be conceptualized within the biopsychosocial model as including physical, psychological, and social dimensions. Physical boundaries are those established in terms of physical closeness to others—who we allow to touch us or how close we want others to stand near us.

Psychological boundaries are established in terms of emotional distance from others—how much of our innermost feelings and thoughts we want to share. Social boundaries, such as norms, customs, and roles, help us establish our closeness and place within the family, culture, and community. Boundaries are not fixed but dynamic. When boundaries are involuntarily infringed upon, the individual feels threatened and responds to the perceived threat. The nurse must elicit permission before implementing interventions that invade the patient's personal space.

Personal Boundaries

Every individual is surrounded by four different body zones that provide varying degrees of protection against unwanted physical closeness during interactions. These were identified by Hall (1990) as the intimate zone (e.g., for whispering and embracing), the personal zone (e.g., for close friends), the social zone (e.g., for acquaintances), and the public zone (usually for interacting with strangers) (Fig. 10.4). The actual sizes of the different zones vary according to culture. Some cultures define the intimate zone narrowly and the personal zones widely. Thus, friends in these cultures may stand and sit close while interacting. People of other cultures define the intimate zone widely and are uncomfortable when others stand close to them.

The variability of intimate and personal zones has implications for nursing. For a patient to be comfortable with a nurse, the nurse needs to protect the intimate zone of that individual. The patient usually will allow the nurse to enter the personal zone but will express discomfort if the nurse breaches the intimate zone. For the nurse, the difficulty lies in differentiating the personal zone from the intimate zone for each patient.

Figure 10.4: Body space zones.

The nurse's awareness of their own need for intimate and personal space is

another prerequisite for therapeutic interaction with the patient. It is important that a nurse feel comfortable while interacting with patients. Establishing a comfort zone may well entail fine-tuning the size of body zones. Recognizing this will help the nurse understand occasional inexplicable reactions to the proximity of patients.

Professional Boundaries and Ethics

For nurses, professional boundaries are also essential to consider in the context of the nurse–patient relationship. Patients often enter such relationships at a very vulnerable point, and nurses need to be aware of professional boundaries to avoid exploitation of the patient. For example, in a friendship, there is a two-way sharing of personal information and feelings, but as mentioned previously, in a nurse–patient relationship, the focus is on the patient’s needs, and the nurse generally does not share personal information or attempt to meet their own needs through the relationship. The patient may seek a friendship or sexual relationship with the nurse (or vice versa), but this would be inconsistent with the professional role and is usually considered unethical.

Indicators that the relationship may be moving outside the professional boundaries are gift giving on either party’s part, spending more time than usual with a particular patient, strenuously defending or explaining the patient’s behavior in team meetings, the nurse feeling that they are the only one who truly understands the patient, keeping secrets, or frequently thinking about the patient outside of the work situation (Forchuk et al., 2006). State or provincial regulatory bodies will have either guidelines or firm rules regarding any legal or professional restrictions about the amount of time that must pass prior to engaging in a romantic or sexual relationship with a former patient. Guidelines are comparatively vague about when a friendship would be appropriate, but such relationships are not appropriate when the nurse is actively providing care to the patient. Exceptions may be when a relationship preceded the nursing context and another nurse is unavailable to provide care, such as in a rural area. Similarly, relationships to meet the nurse’s needs that are acquired through the nursing context, such as a relationship with a family member of the patient, also breach professional boundaries. When concerns arise related to therapeutic boundaries, the nurse must seek clinical supervision or transfer the care of the patient immediately.

Defense Mechanisms

When communicating with patients, it is also important for the nurse to be aware of the defense mechanisms that patients may use. Defense mechanisms (also known as coping styles) are psychological mechanisms that help an individual respond to and cope with difficult situations, emotional conflicts, and external stressors. While defense mechanisms might seem to indicate the existence of problematic mental state, this is not true. Healthy individuals in many different contexts use defense mechanisms. The use of defense mechanisms may be conscious or unconscious. Some defense mechanisms (e.g., projection, splitting, acting out) are mostly maladaptive. Others (e.g., suppression, denial) may be either maladaptive or adaptive depending on the context in which they occur. The use of defense mechanisms becomes maladaptive when its persistent use interferes with the person's ability to function and their quality of life (see [Table 10.4](#)).

For example, responding to a difficult life event altruistically is very often a healthy way to recover. On the other hand, defense mechanisms such as acting out, autistic fantasies, projection, and splitting are rarely adaptive. A defense mechanism such as repression can be a natural way to react to a traumatic experience, specifically when used in appropriate moderation. However, the unchecked repression of difficult thoughts or feelings can keep someone from coming to terms with their experiences. In developing a successful therapeutic relationship, and in establishing open communication, such knowledge of defense mechanisms will prove itself invaluable.

As nurses develop therapeutic relationships, they will recognize their patients using defense mechanisms. With experience, the nurse will evaluate the purpose of a defense mechanism and then determine whether or not it should be discussed with the patient. For example, if a patient is using humor to alleviate an emotionally intense situation, that may be very appropriate. On the other hand, if someone continually rationalizes antisocial behavior, the use of the defense mechanism should be discussed.

NCLEXNOTE When studying defense mechanisms, focus on mechanisms and coping styles that are similar. For example, displacement versus devaluation versus projection should be differentiated. Identify these mechanisms in your process recordings.

COMMUNICATION CONSIDERATIONS FOR PATIENTS WITH MENTAL HEALTH CHALLENGES

For patients with specific, known mental health problems or illnesses, the nurse must consider how these issues may impact communication and be prepared to analyze the content of nurse–patient interactions.

Table 10.4: SPECIFIC DEFENSE MECHANISMS AND COPING STYLES

The following defense mechanisms and coping styles are commonly used when the individual deals with emotional conflict or stressors (either internal or external).

Defense Mechanism	Definition	Example
Acting out	Using actions rather than reflections or feelings during periods of emotional conflict	A teenager gets mad at his parents and begins staying out late at night.
Affiliation	Turning to others for help or support (sharing problems with others without implying that someone else is responsible for them)	An individual has a fight with her spouse and turns to her best friend for emotional support.
Altruism	Dedicating life to meeting the needs of others (receives gratification either vicariously or from the response of others)	After being rejected by her boyfriend, a young girl joins the Peace Corps.
Anticipation	Experiencing emotional reactions in advance or anticipating consequences of possible future events and considering realistic, alternative responses or solutions	A mother cries for 3 weeks before her last child leaves for college.
Autistic fantasy	Excessive daydreaming as a substitute for human	A young man sits in his room all day and

	relationships, more effective action, or problem-solving	dreams about being a rock star instead of attending a baseball game with a friend.
Denial	Refusing to acknowledge some painful aspect of external reality or subjective experience that would be apparent to others (<i>Psychotic denial</i> is used when there is gross impairment in reality testing.)	A teenager's best friend moves away, but the adolescent says he does not feel sad.
Devaluation	Attributing exaggerated negative qualities to self or others	A boy has been rejected by his long-time girlfriend. He tells his friends that he realizes that she is stupid and ugly.
Displacement	Transferring a feeling about, or a response to, one object onto another (usually less threatening) substitute object	A woman has an argument with her boss. She comes home from work and yells at her children.
Dissociation	Experiencing a breakdown in the usually integrated functions of consciousness, memory, perception of self or the environment, or sensory and motor behavior	An adult relates severe sexual abuse experienced as a child but does it without feeling. She says that the experience was as if she were outside her body watching the abuse.
Help-rejecting	Complaining or making repeated requests for help that disguise covert feelings of hostility or reproach toward others, which are then expressed by rejecting the suggestions, advice, or help that others offer (Complaints or requests may involve physical or	A college student asks a teacher for help after receiving a bad grade on a test. Every suggestion the teacher has is rejected by the student.

	psychological symptoms or life problems.)	
Humor	Emphasizing the amusing or ironic aspects of the conflict or stressor	A person makes a joke right after experiencing an embarrassing situation.
Idealization	Attributing exaggerated positive qualities to others	An adult falls in love and fails to see the negative qualities in the other person.
Intellectualization	Excessive use of abstract thinking or the making of generalizations to control or minimize disturbing feelings	After rejection in a romantic relationship, the rejected explains the relationship dynamics to a friend.
Isolation of affect	Separation of ideas from the feelings originally associated with them	The individual loses touch with the feelings associated with a rape while remaining aware of the details.
Omnipotence	Feeling or acting as if one possesses special powers or abilities and is superior to others	An individual tells a friend about personal expertise in the stock market and the ability to predict the best stocks.
Passive aggression	Indirectly and unassertively expressing aggression toward others. There is a facade of overt compliance masking covert resistance, resentment, or hostility.	One employee doesn't like another, so he secretly steals her milk from the office refrigerator. She is unaware of his hostile feelings.
Projection	Falsely attributing to another one's own unacceptable feelings, impulses, or thoughts	A child is very angry at a parent but accuses the parent of being angry.
Projective identification	Falsely attributing to another one's own unacceptable feelings, impulses, or thoughts. Unlike	A child is mad at a parent, who in turn becomes angry at the

	<p>simple projection, the individual does not fully disavow what is projected. Instead, the individual remains aware of their own affect or impulses but misattributes them as justifiable reactions to the other person. Frequently, the individual induces the very feelings in others that were first mistakenly believed to be there, making it difficult to clarify who did what to whom first.</p>	<p>child but may be unsure of why. The child then feels justified at being angry with the parent.</p>
Rationalization	<p>Concealing the true motivations for one's own thoughts, actions, or feelings through the elaboration of reassuring or self-serving but incorrect explanations</p>	<p>A man is rejected by his girlfriend but explains to his friends that her leaving was best because she was beneath him socially and would not be liked by his family.</p>
Reaction formation	<p>Substituting behavior, thoughts, or feelings that are diametrically opposed to one's own unacceptable thoughts or feelings (this usually occurs in conjunction with their repression)</p>	<p>A wife finds out about her husband's extramarital affairs and tells her friends that she thinks his affairs are perfectly appropriate. She truly does not feel, on a conscious level, any anger or hurt.</p>
Repression	<p>Expelling disturbing wishes, thoughts, or experiences from conscious awareness (The feeling component may remain conscious, detached from its associated ideas.)</p>	<p>A woman does not remember the experience of being raped in the basement but does feel anxious when going into that house.</p>
Self-assertion	<p>Expressing feelings and thoughts directly in a way that is not</p>	<p>An individual reaffirms that going to a ball</p>

	coercive or manipulative	game is not what she wants to do.
Self-observation	Reflecting feelings, thoughts, motivation, and behavior and responding to them appropriately	An individual notices an irritation at his friend's late arrival and decides to tell the friend of the irritation.
Splitting	Compartmentalizing opposite affect states and failing to integrate the positive and negative qualities of the self or others into cohesive images	Self and object images tend to alternate between polar opposites: exclusively loving, powerful, worthy, nurturing, and kind or exclusively bad, hateful, angry, destructive, rejecting, or worthless. One friend is wonderful and another former friend, who was at one time viewed as being perfect, is now believed to be an evil person.
Sublimation	Channeling potentially maladaptive feelings or impulses into socially acceptable behavior	An adolescent boy is very angry with his parents. On the football field, he tackles someone very forcefully.
Suppression	Intentionally avoiding thinking about disturbing problems, wishes, feelings, or experiences	A student is anxiously awaiting test results but goes to a movie to stop thinking about it.
Undoing	Words or behavior designed to negate or to make amends symbolically for unacceptable thoughts, feelings, or actions	A man has sexual fantasies about his wife's sister. He takes his wife away for a romantic weekend.

Considering Specific Mental Health Issues

It is important to consider the individual's mental health challenges when selecting specific communication strategies. For example, patients with increased levels of anxiety may have poor communication, requiring the nurse to use shorter and simpler statements or questions.

Patients who are experiencing depression may have difficulty articulating their feelings, or their thinking and responses may be slowed. The nurse will frequently use silence and empathic techniques throughout this interaction. The person who is depressed may also use communication styles such as overgeneralizing ("This always happens to me. ... Everything always turns out for the worse."). The nurse can assist the patient and ask them to be more specific (e.g., asking about a specific time or a specific exception).

Patients with schizophrenia may exhibit symptoms such as hallucinations or delusions. If a person is having auditory hallucinations (hearing sounds that are imagined), the nurse's voice may be one of several the patient is hearing. Clear, short sentences may assist in getting the patient's attention on the nurse's voice. A person experiencing delusions may use pronouns vaguely ("they" did it) or other forms of vague or unclear communication. Clarifying and assisting the patient to be more specific may assist the patient's thinking as well as communication.

As you read through the chapters on various psychiatric disorders, consider how the signs and symptoms of each illness could have an impact on communication and the evolving therapeutic relationship.

Analyzing Interactions

Many patients with psychiatric disorders have difficulty communicating. They may have perceptual, cognitive, and information-processing deficits that interfere with their ability to express ideas, understand concepts, and accurately perceive the environment (Pounds, 2017). Because of the complexity of communication, mental health professionals monitor their interactions with patients using various methods, including audio recording, video recording, and **process recording**, which entails writing a verbatim transcript of the interaction. A video or audio recording of an interaction provides the most accurate

monitoring but is cumbersome to use. Process recording, one of the easiest methods to use, is adequate in most situations. Nurses should use it when first learning therapeutic communication and during times when communication becomes a problem. In a process recording, the nurse records, from memory, the verbatim interaction immediately after the communication (Table 10.5). Nonverbal communication, by both the patient and the nurse, should also be recorded.

The nurse then analyzes the content of the interaction in terms of the words and their meaning for both the patient and the nurse. The analysis is especially important because the ability to communicate is often compromised in people with mental disorders. Because words may not have the same meaning for the patient as they do for the nurse, clarification of meaning becomes especially important. The analysis can identify symbolic meanings, **content themes**, and blocks in communication.

Table 10.5: PROCESS RECORDING

Setting: The living room of Mr. S's home. Mr. S is 23 years old and was hospitalized for 2 weeks. His diagnosis is a bipolar mood disorder, and he is recovering from a depressive episode. His parents are in the room but cannot hear the conversation. Mr. S is sitting on the couch, and the nurse is sitting on a chair. This is the nurse's first visit after Mr. S's discharge from the hospital.

Patient	Nurse	Interpretation/Analysis
	How are you doing, Mr. S? (smiles and offers hand to shake)	<i>Plan:</i> Initially develop a sense of trust and initiate a therapeutic relationship.
I'm fine. It's good to be home (looking at floor, takes nurse's hand to briefly shake). I really don't like the hospital (shakes his head while still	You didn't like the hospital?	<i>Interpretation:</i> Validating assumption that Mr. S does not want to return to hospital. Nonverbal communication may indicate sadness or low self-esteem. This needs further exploration.

looking at
floor).

No. The nurses
lock you up
(maintains eye
contact with
nurse,
frowning, arms
crossed). Are
you a nurse?

I'm a nurse. I'm wondering if you
think that I will lock you up
(maintains eyecontact and open
posture).

Patient validates
assumption regarding
hospital, but nonverbal
behavior indicates there
may be further concerns.

Interpretation: Mr. S may
be wondering what my role
is and whether I will put
him back in the hospital.
This assumption needs to
be validated, and my role
needs clarification.

You could tell my mom to put me back in the hospital
(maintains eye contact with nurse).

Any treatment that I recommend will
be thoroughly discussed with you
first. I am here to help you stay out of
the hospital. I will not discuss
anything with your mother unless you
give me permission to do so (nurse
maintains eye contact and open
posture).

Use interpretation to
clarify Mr. S's thinking.
Mr. S is wondering about
my relationship with his
mother. Explain my role
and confidentiality.

(Patient
maintains eye
contact and
uncrosses
arms.)

Patient's nonverbal
communication appears to
indicate he is more
comfortable with this
clarification.

Symbolism

Symbolism, the use of a word or phrase to represent an object, event, or feeling, is used universally. For example, automobiles are named for wild animals that represent speed, prowess, and beauty. In people with mental disorders, the use of words to symbolize events, objects, or feelings is often idiosyncratic, and they

cannot explain their choices. For example, a person who is feeling scared and anxious may tell the nurse that bombs and guns are exploding. It is up to the nurse to make the connection between the bombs and guns and the patient's feelings and then validate this with the patient. Because of the patient's cognitive limitations, the individual may express feelings only symbolically. Another example is found in [Table 10.6](#).

Some patients, for example, those with developmental disabilities or organic brain difficulties, may have difficulty with abstract thinking and symbolism. Conversations may be interpreted literally. For example, in response to the question "What brings you to the hospital?" a patient might reply, "The ambulance." In these situations, the nurse must be cautious to avoid using symbols or metaphors. Concrete language, that is, language reflecting what can be observed through the senses, will be more easily understood.

Content Themes

Verbal behavior is also interpreted by analyzing content themes. Patients often express concerns or feelings repeatedly in several different ways. After a few sessions, a common theme emerges. Themes may emerge symbolically, as in the case with the patient who constantly talks about the "guns and bombs." Alternatively, a theme may simply be identified as a recurrent thread of a story that a patient retells at each session. For example, one patient often discussed his early abandonment by his family. This led the nurse to hypothesize that he had an underlying fear of rejection. The nurse was then able to test whether there was an underlying fear and to develop strategies to help the patient explore the fear ([Box 10.4](#)). It is important to involve patients in analyzing themes so they may learn this skill. Within the therapeutic relationship, the person who does the work is the one who develops the competencies, so the nurse must be careful to share this opportunity with the patient (Peplau, 1952, 1992).

BOX 10.4

Themes and Interactions

Session 1: Patient discusses the death of his mother at a young age.

Session 2: Patient explains that his sister is now married and never visits him.

Session 3: Patient says that his best friend in the hospital was discharged and he really misses her.
Session 4: Patient cries about a lost kitten.
Interpretation: Theme of loss is pervasive in several sessions.

Communication Blocks

Communication blocks are identified by topic changes that either the nurse or the patient makes. Topics are changed for various reasons. A patient may change the topic from one that does not interest him to one that he finds more meaningful. However, an individual usually changes the topic because they are uncomfortable with a particular subject. When a topic change is identified, the nurse or patient hypothesizes the reason for it. If the nurse changes the topic, they need to determine why. The nurse may find that they are uncomfortable with the topic or may not be listening to the patient. Novice mental health nurses, who are uncomfortable with silences or trying to elicit specific information from the patient, often change topics. When communication blocks are recognized, the nurse should attempt to redirect the conversation back to the topic at hand unless the particular topic is too uncomfortable for the patient at that point in time.

Table 10.6: USE OF SYMBOLISM

Setting: Mr. A has been diagnosed with schizophrenia and expresses himself through the use of television characters. A nurse observed another patient shoving him against the wall. As the nurse approached the two patients, the other patient ran, leaving Mr. A noticeably shaking. The nurse checked to see if Mr. A was all right.

Patient	Nurse	Interpretation/Analysis
Robin Hood saved the day. (trembling, arms crossed)	Mr. A, are you OK? (approaches patient)	Mr. A could not say, "Thank you for helping me." Instead, he could only describe a fictional character's response.
	You feel that you are saved?	The nurse focused on what Mr. A must be feeling if he

It's a glorious day in
Sherwood Forest!
(trembling decreases;
smiles at nurse)

felt that he had been rescued.
He seems to be happy now.

Mr. A, are you hurting
anywhere? (Eyes scan
over patient, using
concerned tone of
voice.)

The nurse wanted to check
whether the patient had been
hurt when pushed against the
wall.

The angel of mercy put
out the fire(continues to
smile and extends hand to
shake hands with nurse).

The patient is apparently not
hurting now.

The nurse must also record and interpret the patient's nonverbal behavior in light of the verbal behavior. Is the patient communicating one thing verbally and another nonverbally? The nurse must consider the patient's cultural background. Is the behavior consistent with cultural norms? For example, if a patient denies any problems but is affectionate and physically demonstrative (which is antithetical to their naturally stoic cultural beliefs and behaviors), the nonverbal behavior is inconsistent with what is normal behavior for that person. Further exploration is needed to determine the meaning of the culturally atypical behavior.

THE NURSE–PATIENT RELATIONSHIP

The nurse–patient relationship is a dynamic process that changes with time. It can be viewed in steps or phases with characteristic behaviors for both patient and nurse. This text uses an adaptation of Hildegard Peplau's model, which she introduced in her seminal work, *Interpersonal Relations in Nursing* (1952, 1992). Emerging evidence suggests that a well-developed nurse–patient relationship positively affects patient care.

Introduction

The nurse–patient relationship begins with the initial introduction. Nurses initiate the introduction by simply explaining their role and their task—an initial assessment or an invitation to a group. It is very important to introduce oneself. The language used is also very important. The nurse should be sensitive to using patient-centered and gender-neutral language. When first meeting a patient, do not assume gender or sexual orientation by the clothing or appearance. If you are unsure of the patient’s gender but must use pronouns, the terms “they/them/their” are preferable to terms that make patients select a male or female category (Sullivan et al., 2017).

Phases

The nurse–patient relationship is conceptualized in three overlapping phases that evolve with time: **orientation phase**, **working phase**, and **resolution phase**. The orientation phase is the phase during which the nurse and patient get to know each other. During this phase, which can last from a few minutes to several months, the patient develops a sense of trust in the nurse. The second is the working phase, in which the patient uses the relationship to examine specific problems and learn new ways of approaching them. The final stage, resolution phase, is the termination stage of the relationship and lasts from the time the problems are actually resolved to the close of the relationship. The relationship does not evolve as a simple linear relationship. Instead, the relationship may be predominantly in one phase, but reflections of all phases can be seen in each interaction ([Table 10.7](#)).

Table 10.7:

PHASES OF THE NURSE–PATIENT RELATIONSHIP

Orientation	Working	Resolution
PatientSeeks assistance	Discusses problems and	May express ambivalence
Identifies needs	underlying needs	about the relationship and
Commits to a	Uses emotional safety of its termination

begins to test	Tests new ways of	

	relationship	solving problems Feels comfortable with nurse May use transference	
Nurse	Actively listens Establishes boundaries of the relationship Clarifies expectations Identifies countertransference issues Uses empathy Establishes rapport	Supports development of healthy problem-solving Encourages patient to prepare for the future	Avoids returning to patient's initial problems Encourages independence Promotes positive family interactions

KEY CONCEPTS The nurse–patient relationship is a dynamic process that changes with time. It can be viewed in steps or phases with characteristic behaviors for both the patient and the nurse.

Orientation Phase

The orientation phase begins when the nurse and patient meet and ends when the patient begins to identify the problems to be examined. During the orientation phase, the nurse discusses the patient's expectations, explains the purpose of the relationship and its boundaries, and facilitates the development of the relationship. It is natural for the nurse to be nervous during the first few sessions. The goal of the orientation phase is to develop trust and security within the nurse–patient relationship. During this initial phase, the nurse listens intently to the patient's history and perception of problems and begins to understand the patient and identify themes. The use of empathy facilitates the development of a positive therapeutic relationship.

First Meeting

During the first meeting, outlining both nursing and patient responsibilities is important. The nurse is responsible for providing guidance throughout the therapeutic relationship, protecting confidential information, and maintaining professional boundaries. The patient is responsible for attending agreed-upon sessions, interacting during the sessions, and participating in the nurse–patient

relationship. The nurse should also explain clearly to the patient meeting times, handling of missed sessions, and the estimated length of the relationship. Issues related to recording information and how the nurse will work within the interdisciplinary team should also be made explicit.

Usually, both the nurse and the patient feel anxious at the first meeting. The nurse should recognize the anxieties and attempt to alleviate them before the meeting. The patient's behavior during this first meeting may indicate to the nurse some of the patient's problems in interpersonal relationships. For example, a patient may talk nonstop for 15 minutes or may brag of sexual conquests. What the patient chooses to tell or not to tell is significant. What a patient first does or says may not accurately indicate their true feelings or the situation. In the beginning, patients may deny problems or employ various forms of defense mechanisms or prevent the nurse from getting to know them. The patient is usually nervous and insecure during the first few sessions and may exhibit behavior reflective of these emotions, such as rambling. Typically, by the third session, the patient can focus on a topic.

Confidentiality in Treatment

Ideally, nurses include people who are important to the patient in planning and implementing care. The nurse and patient should discuss the issue of confidentiality in the first session. The nurse should be clear about any information that is to be shared with anyone else. The nurse shares significant assessment data and patient progress with a supervisor, team members, and a physician. Most patients expect the nurse to communicate with other mental health professionals and are comfortable with this arrangement. Restrictions regarding what can be shared and with whom are also covered by state or provincial mental health acts and health information acts.

Testing the Relationship

This first part of the orientation phase, called the "honeymoon phase," is usually pleasant. However, the therapeutic team typically hits rough spots before completing this phase. The patient begins to test the relationship to become convinced that the nurse will really accept them. Typical "testing behaviors" include forgetting a scheduled session or being late. Patients may also express anger at something a nurse says or accuse the nurse of breaking confidentiality.

Another common pattern is for the patient to first introduce a relatively superficial issue as if it is the major problem. The nurse must recognize that these behaviors are designed to test the relationship and establish its parameters, not to express rejection or dissatisfaction with the nurse. The student nurse often feels personally rejected during the patient's testing and may even become angry with the patient. If the nurse simply accepts the behavior and continues to be available and consistent to the patient, these behaviors usually subside. Testing needs to be understood as a normal way that human beings develop trust.

Working Phase

When the patient begins identifying problems to work on, the working phase of the relationship has started. Problem identification can yield a wide range of issues, such as managing symptoms of a mental disorder, coping with chronic pain, examining issues related to sexual abuse, or dealing with problematic interpersonal relationships. Through the relationship, the patient begins to explore the identified problems and develop strategies to resolve them. By the time the working phase is reached, the patient has developed enough trust that they can examine the identified problems within the security of the therapeutic relationship. In the working phase, the nurse can use various verbal and nonverbal techniques to help the patient examine problems and to support the patient through the healing process.

Transference (unconscious assignment to others of the feelings and attitudes that the patient originally associated with important figures) and **countertransference** (the provider's emotional reaction to the patient based on personal unconscious needs and conflicts) become important issues in the working phase. For example, a patient could be hostile to a nurse because of underlying resentment of authority figures; the nurse, in turn, could respond defensively because of earlier experiences of anger. The patient uses transference to examine problems. During this phase, the patient is psychologically vulnerable and emotionally dependent on the nurse. The nurse needs to recognize countertransference and prevent it from eroding professional boundaries.

Often, nurses are eager to implement rehabilitation plans. However, this cannot be done until the patient trusts the nurse and identifies what issues they wish to work on in the context of the relationship.

Resolution Phase

The final stage of the nurse–patient relationship is resolution, which begins when the actual problems are resolved and ends with the termination of the relationship. During this phase, the patient is redirected toward a life without this specific therapeutic relationship. The patient connects with community resources, solidifies a newly found understanding, and practices new behaviors. The patient takes responsibility for follow-up appointments and interacts with significant others in new ways. New problems are not addressed during this phase except in terms of what was learned during the working stage. The nurse assists the client in strengthening relationships, making referrals, and recognizing and understanding signs of future relapse.

Termination begins on the first day of the relationship, when the nurse explains that this relationship is time limited and has been established to resolve the patient's problems and help them handle their problems. Because a therapeutic relationship is dependent, the nurse must constantly evaluate the patient's level of dependence and continually support the patient's move toward independence. Termination is usually stressful for the patient, who must sever ties with the nurse who has shared thoughts and feelings and given guidance and support over many sessions.

Depending on previous experiences with terminating relationships, some patients may not handle their emotions well during termination. Some may not show up for the last session at all to avoid their feelings of sadness and separation. Many patients display anger about the relationship's ending. Patients may express anger toward the nurse or displace it onto others. For example, a patient may shout obscenities at another patient after being told that his therapeutic relationship with the nurse would end in a few weeks. One of the best ways to handle the anger is to help the patient acknowledge it, to explain that anger is a normal emotion when a relationship is ending, and to reassure the patient that it is acceptable to feel angry. The nurse should also reassure the patient that anger subsides after the relationship is over.

Another typical termination behavior is raising old problems that have already been resolved. The nurse may feel frustrated if patients in the termination phase present resolved problems as if they were new. The nurse may feel that the sessions were unsuccessful. In reality, patients are attempting to prolong the relationship and avoid its ending. Nurses should avoid addressing these

problems. Instead, they should reassure patients that they already covered those issues and learned methods to control them. They should explain that the patient may be feeling anxious about the relationship's ending and redirect the patient to newly found skills and abilities in forming new relationships, including support groups and social groups. The final meeting should focus on the future (Box 10.5). The nurse can reassure the patient that the nurse will remember them, but the nurse should not agree to see the patient outside the relationship.

Nontherapeutic Relationships

Although it is hoped that all nurse–patient relationships will go through the phases of the relationship described earlier, this is not always the case. In a **nontherapeutic relationship**, the nurse and the patient both feel very frustrated and keep varying their approach with each other in an attempt to establish a meaningful relationship. This is different from a prolonged orientation phase in that the efforts are not sustained; rather, they vary constantly.

The nurse may try longer meetings, shorter meetings, being more or less directive, and varying the therapeutic stance from warm and friendly to aloof. Patients in this phase may try to talk about the past but then change to discussions of the “here and now.” They will try talking about their family and in the next meeting talk about their work goals. Both *grapple and struggle* to come to a common ground, and both become increasingly frustrated with each other.

Eventually, the frustration becomes so great that the pair gives up on each other and moves to a phase of *mutual withdrawal*. The nurse may schedule seeing this patient at the end of the shift and “run out of time” so the meeting never happens. The patient will leave the unit or otherwise be unavailable during scheduled meeting times. If a meeting does occur, the nurse will try to keep it short, thinking, “What’s the point—we just cover the same old ground anyway.” The patient will attempt to keep it superficial and stay on safe topics (“You can always ask about your medications—nurses love to health teach, you know.”).

BOX 10.5

Transitional Relationship Model

Forchuk, C., Martin, M. L., Jensen, E., Ouseley, S., Sealy, P., Beal, G., et al. (2013). *Integrating an*

evidence-based intervention into clinical practice: 'Transitional relationship model.' Journal of Psychiatric and Mental Health Nursing, 20(7), 584–594.

THE QUESTION: The Transitional Relationship Model (TRM) facilitates an effective discharge from the hospital to the community. Given this, what is the most effective way of implementing this model? What might facilitate the successful implementation of the TRM? What are the barriers to successful implementation?

METHODS: This study implemented the TRM in three waves, across six wards using a delayed implementation control group design to study how the addition of new information changed the implementation of the TRM. Following the experiences of the wards in which the TRM was initially implemented, recommendations for successful implementation of the model were developed for the subsequent waves of wards. Recommendations were developed using a combination of qualitative methods: monthly summaries, progress reports, meeting minutes, and focus groups.

FINDINGS: The results of this study can be divided into two categories: facilitators and barriers. The successful implementation of the TRM was aided by the use of educational modules (for both staff and peer training), on-site champions, and supportive documentation systems. Barriers included feeling swamped or overwhelmed, “death by process,” preexisting conflicts within teams, and changes in champions.

IMPLICATIONS FOR NURSING: The positive health outcomes associated with the TRM require careful preparation and constant attention to education, communication, and the effectiveness of the support given to caregivers.

A **deteriorating relationship** is also nontherapeutic and has been shown to have predictable phases (Coatsworth-Puspoky et al., 2006). This relationship starts in the *withholding* phase, during which the nurse is perceived as “withholding” nursing support. The nurse fails to recognize that the patient is a person with an illness or health needs. The patient feels uncomfortable, anxious, frustrated, and guilty about being ill and does not develop a sense of trust. A barrier exists between the patient and the nurse.

The middle phase of a deteriorating relationship consists of two subphases: *avoiding* and *ignoring*. The patient begins to avoid the nurse and perceives that the nurse is avoiding them. The patient abides by the rules because they do not want to cause problems. The nurse is perceived as rude and condescending. The nurse ignores and avoids the patient’s requests for help; in turn, the patient becomes more anxious, frustrated, and fearful. Patients experiencing this phase report feelings of wanting to give up, being rejected, not being cared for, and not being listened to.

The end phase is named *struggling with and making sense of*. In the final phase of a nontherapeutic, deteriorating relationship, the patient struggles with and tries to understand the unsatisfactory relationship. The patient feels hopeless

and frustrated as a result of the lack of support received by the nurse. In a deteriorating relationship, the patient and nurse begin as strangers and end as enemies.

Obviously, no therapeutic progress can be made in a nontherapeutic or deteriorating relationship. The nurse may be hesitant to ask for a therapeutic transfer, assuming that a relationship would similarly fail with another nurse. However, each relationship is unique, and difficulties in one relationship do not predict difficulties in the next. Clinical supervision early on may assist the development of the relationship, but often a therapeutic transfer to another nurse is required.

EXAMPLES OF STRATEGIES RELATED TO THERAPEUTIC RELATIONSHIPS

Motivational Interviewing

Motivational interviewing (MI) is a clinical method intended to engage a patient's own decision-making ability. By focusing and reinforcing the client's own arguments for change, MI can be used to achieve positive outcomes. This is a collaborative process involving directed counseling and focused discussions between the care provider and the patient. As a result, MI is inherently exploratory and adaptive.

There is a lot of evidence to suggest that MI produces positive health outcomes; however, more studies that explore the long-term outcomes and cost effectiveness of MI are needed (Frost et al., 2018). A review of other published reviews by DiClemente et al. (2017) indicated that MI and similar interventions can have varying degrees of efficacy. For example, substantial empirical evidence exists for MI in reducing alcohol, marijuana, and tobacco use, but there is limited support regarding its effectiveness in reducing cocaine, opiate, and methamphetamine use and issues with gambling. Because much of the success of MI depends on the quality of interaction between the care provider and the patient, good communication practices are essential for effective implementation of MI. Many of these problems are the result of the assumption that high-risk behaviors are entirely or mostly under the control of the individual (Berg et al., 2011). Careful attention to the effects of this assumption can make clear where MI may or may not be an ideal treatment option.

Because the success of MI is, in part, dependent on contingent factors, care providers require frequent instruction and feedback. Strong communication in the context of therapeutic relationships as discussed in this chapter, especially self-awareness, empathetic linkages, active listening, and the avoidance of unhelpful varieties of defense mechanisms, requires ongoing training and will affect therapeutic outcomes. While challenging to successfully implement, MI has produced positive health outcomes in many different settings (Dean et al., 2016; Ekong & Kavookjian, 2016; Wade et al., 2019; Wong-Anuchit et al., 2019). Every particular use of MI is likely to vary according to patient needs; Miller and Moyers (2006) have identified eight features of MI that should appear in every application of this technique:

1. Openness to collaboration with clients' own expertise,
2. Proficiency in client-centered counseling, including accurate empathy,
3. Recognition of key aspects of client speech that guides the practice of MI,
4. Eliciting and strengthening client change talk,
5. Rolling with resistance,
6. Negotiating change plans,
7. Consolidating client commitment, and
8. Switching flexibly between MI and other intervention styles. (p. 3)

Transitional Relationship Model/Transitional Discharge Model

The Transitional Relationship Model (TRM) is theoretically grounded in the work of Hildegard Peplau; healing occurs in relationships. Therapeutic relationships can be formed with either professionals or peer supporters. The TRM was first developed to ease the transition from hospital to community, but its use has now been expanded to a variety of transitional care processes. There are two essential components of the TRM:

1. The therapeutic relationship should be extended until a new relationship with another care provider is established (continuing relationships formed in the hospital until new therapeutic relationships in the community are formed).
 2. Trained peer support (often through a consumer survivor group) from a psychiatric survivor who has now successfully transitioned to the community.
- In addition to producing positive therapeutic outcomes, the TRM also reduces

time spent in hospital, the number of readmissions (Reynolds et al., 2004), and costs to the health care system (Forchuk et al., 2019) (see [Box 10.6](#)).

Technology and the Therapeutic Relationship

As technology develops and becomes increasingly accessible, traditional face-to-face communication can be replaced with technologic interactions. Situations such as the coronavirus disease 2019 (COVID-19) pandemic have quickly accelerated mental health services moving to a virtual environment. Telehealth modalities can include phone and video conferencing, mental health apps, and internet-delivered programs (Reay et al., 2020). Studies have found telephone or video conferencing to be as effective as standard in-person treatment for a variety of mental health disorders, particularly depression and anxiety disorders (Varker et al., 2019). Telehealth is a useful alternative for individuals living in rural and other underserved areas, those perceiving stigma associated with going to a provider's office, and those lacking reliable transportation (Goldin et al., 2021; Hasselberg, 2020). Patients report many advantages to receiving virtual care, including accessibility, convenience, cost-effectiveness, and privacy (Reay et al., 2020).

There are barriers to telehealth. Establishing a therapeutic relationship can take longer due to a lack of physical presence. Nonverbal communication, such as gestures, mannerisms, and tone, is more difficult to assess when not communicating in person (Reay et al., 2020). Misinterpretation of body language and behavioral manifestations may result in an inaccurate assessment of the patient (Goldin et al., 2021). Telepsychiatry is not appropriate when a patient's safety is an imminent risk. It is also less effective in individuals with severe mental illness who have diminished cognitive abilities and impaired insight (Reay et al., 2020). Lack of technology or unreliable internet access is another barrier. It is critical for communication over the internet to be HIPAA compliant and secure to maintain confidentiality. Many cheaper hardware devices may have "bloatware" that tracks information, and similarly "free" or cheap software may sell information to third parties. Hospital firewalls can be useful in establishing such connections (Forchuk et al., 2012). One must always be aware of a community agency, hospital, or research site's policies and best practices regarding communication online. Some commonly used platforms for online communication, such as Facebook Messenger, cannot meet privacy standards

and should not be used in communication with patients. However, the internet is an invaluable resource for educational and research purposes.

SUMMARY OF KEY POINTS

- To deal therapeutically with the emotions, feelings, and problems of patients, nurses must understand their own values and beliefs and interpersonal strengths and limitations.
 - The nurse–patient relationship is built on therapeutic communication, including verbal and nonverbal interactions between the nurse and the patient. Some communication skills include active listening, positive body language, appropriate verbal responses, and the ability of the nurse to interpret appropriately and analyze the patient’s verbal and nonverbal behaviors.
 - Two of the most important communication concepts are empathy and rapport.
 - In the nurse–patient relationship, as in all types of relationships, certain physical, emotional, and social boundaries and limitations need to be observed.
 - The therapeutic nurse–patient relationship consists of three major and overlapping stages or phases: the orientation phase, in which the patient and nurse meet and establish the parameters of the relationship; the working phase, in which the patient identifies and explores problems; and the resolution phase, in which the patient learns to manage the problems and the relationship is terminated.
 - The nontherapeutic relationship consists of three major and overlapping phases: the orientation phase, the grappling and struggling phase, and the phase of mutual withdrawal. A deteriorating relationship begins with a withholding phase, continues through the phases of avoiding and ignoring, and finally ends unsatisfactorily with a phase named “struggling with and making sense of.”
-

BOX 10.6 • THE LAST MEETING

INEFFECTIVE APPROACH

Ms. J: Why did the other nurses bring you flowers and cards today?

Nurse: Well, that's because today is my last day; I'm transferring to the new hospital, across town.

Ms. J: Oh, um. I was just thinking, I need to talk to you about something important.

Nurse: What is it?

Ms. J: I have been worrying about my medication again.

Nurse: Oh, have you had any side effects?

Ms. J: No, but I might.

Nurse: I think you should tell the new nurse.

Ms. J: She is too new. She won't understand and you helped me last time. I feel so worried about your leaving. Is there any way you can stay? You said that you would check in, remember?

Nurse: Well, I could check on you tomorrow?

Ms. J: Oh, would you? I would really appreciate it if you would give me your new telephone number and that way I can tell you if anything happens.

Nurse: I don't know what the number will be, but you might be able to find it online.

EFFECTIVE APPROACH

Ms. J: Why did the other nurses bring you flowers and cards today?

Nurse: Oh, hello Ms. J. Do you remember? Today is my last day.

Ms. J: Oh, yes. Well, I need to talk to you about something important.

Nurse: We talked about that. Anything "important" needs to be shared with the new nurse.

Ms. J: But I want to tell you. You really made me feel better last time.

Nurse: Thank you but remember that you improved a lot because you know what to do in order to continue progressing. Saying goodbye can be very hard.

Ms. J: I'll miss you.

Nurse: Your feelings are very normal when relationships are ending. I will remember you in a very special way.

Ms. J: Can I please have your telephone number in case I need to talk to you?

Nurse: No, I can't give that to you. It is important that we say goodbye today. And, remember, you can always talk to the new nurse about your concerns.

Ms. J: Okay, I know. Goodbye. Good luck.

Nurse: Goodbye.

CRITICAL THINKING CHALLENGE

- What were some of the mistakes the nurse in the first scenario made?
- In the second scenario, how does therapeutic communication in the termination phase differ from effective communication in the working phase?

Unfolding Patient Stories: Sharon Cole

Part 1

Sharon Cole, a 31-year-old female with bipolar disorder, had a surgical repair of an ankle fracture

sustained in a fall during a manic episode. What verbal and nonverbal communication techniques can be used to establish a therapeutic relationship when she arrives on the orthopedic unit following surgery? Why is it important for the nurse to assess both verbal communication and nonverbal behavior? What methods can be used to facilitate a therapeutic interaction when she is manic, talking constantly, expressing grandiose thoughts that she is needed in Washington, DC to solve political issues, and wanting to leave the hospital? What approaches can block effective communication?

CRITICAL THINKING CHALLENGES

1. Describe how you would do a suicide assessment on a distraught patient who comes to the physician's office expressing concerns about her ability to cope with her current situation. Describe how you would approach this patient if you determined she was suicidal. How might this assessment look different depending on the phase of the therapeutic relationship?
2. Describe how you would communicate with a patient who is concerned that the diagnosis of bipolar disorder will negatively affect their social and work relationships.
3. Your depressed patient does not seem inclined to talk about the depression. Describe the measures you would take to initiate a therapeutic relationship with them.
4. Think of a time that you worked with a patient you did not like. What was behind the dislike? How did you handle the therapeutic relationship? What could you do differently?

Movie Viewing Guides

Joker: 2019. *Joker* is written as a potential origins movie for this popular DC Comics villain. Arthur Fleck, who later in the film becomes known as Joker (Joaquin Phoenix), is a street clown and unsuccessful stand-up comic. He is afflicted with an uncontrollable laughter from an unspecified condition, which has led to institutionalization in the past and ostracization, exclusion, and abuse by society. The movie follows Arthur through a series of events that leads him to cement his identity as Joker.

VIEWING POINTS: A number of critics, including health care professionals, responded to *Joker* with opinion pieces depicting the potentially damaging and

stigmatizing portrayal of mental illness and its association with violence. While it is normal for clients and health care professionals to enter the therapeutic relationship with preconceptions of one another, harmful attitudes and stigmatizing beliefs by the provider can create a barrier to therapeutic communication. How are people with mental illness portrayed in this film? What beliefs could be formed or reinforced about people with mental illness? What evidence exists to support or counter those beliefs (e.g., people with mental illness are violent)? How might your attitudes, beliefs, and preconceptions impact therapeutic communication with a client who has mental illness or a history of violence?

The King's Speech: 2010. This movie centers on the Duke of York/King George VI (Colin Firth), who has experienced incredible frustration with unsuccessful therapies to control his childhood stammer. His wife, the Duchess of York/Queen Elizabeth (Helena Bonham Carter), arranges services with Australian speech therapist and actor Lionel Logue (Geoffrey Rush), with resistance of the duke. Logue demonstrates results in the very first meeting, and over time, creates an atmosphere of trust that permits the Duke to disclose a deep-rooted secret related to his condition.

VIEWING POINTS: Although many differences exist in this relationship, including power, social status, and culture, Logue creates a dynamic of equity and trust from the start. How does Logue close the gap on these differences? What factors contribute to the development of rapport, trust, and safety in the relationship?

Call Me Crazy: A Five Film: 2013. This made-for-TV film follows five individuals and their experience with mental illness. Lucy (Brittney Snow) is a law student who experiences an episode of psychosis after stopping her medication to prove she does not have schizophrenia. She is admitted to a hospital, where she receives individual and group therapy and befriends Bruce (Jason Ritter). The focus turns to another character, Grace (Sarah Hyland), a youth who has been hiding her mother's (Melissa Leo) experience of bipolar disorder from friends but finds support from an unlikely place. The segment on Allison (Sofia Vassilieva) further demonstrates the impact of mental illness on family as she expresses her experience with her sister. Eddie (Mitch Rouse) is a comedian who has been hiding his increasing feelings of depression from his wife, Julia (Lea Thompson). The final individual is Maggie (Jennifer Hudson), a

war veteran who has returned home but has recurrent nightmares following trauma she endured.

VIEWING POINTS: Throughout the film, each character displays defense mechanisms to cope with personal challenges. Identify these coping strategies and determine whether they are healthy or unhealthy. How would the signs and symptoms of each illness impact communication and the therapeutic relationship?

Love and Mercy: 2014. This film details the life of Brian Wilson in two time points: a young Brian Wilson (Paul Dano) in the 1960s as he begins to experience symptoms of auditory hallucinations and mania and an older Brian Wilson (John Cusack) in the 1980s as he was heavily exploited by psychotherapist Dr. Eugene Lundy (Paul Giamatti). A chance encounter with Melinda Ledbetter (Elizabeth Banks) when Brian was purchasing a car leads to a romantic relationship between the two. Melinda is distrustful of Dr. Lundy, who exhibits angry outbursts toward Brian and has him under 24-hour surveillance. With the help of housekeeper Gloria (Diana Maria Riviera) and Brian's brother, Carl Wilson (Brett Davern), Melinda is able to release Brian from Dr. Lundy's control and help him access the care he needs to live a quality life.

VIEWING POINTS: This film demonstrates gross ethical and boundary crossings by a health care professional. What professional boundaries and ethics did Dr. Lundy violate? What guidelines are available in your jurisdiction that describe professional boundaries and ethics in the therapeutic relationship and how would you incorporate these in your care?

Good Will Hunting: 1997. Robin Williams plays a therapist, Dr. Sean Maguire. His patient, Will Hunting (Matt Damon), is a janitor at MIT who is a troubled genius. Through a strong relationship, Will begins to realize his potential. This film deals with intense blocks to communication, as well as issues around justice system use and class.

VIEWING POINTS: Watch closely how the relationship develops between the characters played by Williams and Damon. How does the relationship change as the characters move through different stages of their relationship? Do you think that the level of self-disclosure depicted is therapeutic?

Silver Linings Playbook: 2012. This film portrays one man's struggle to return to society after he is released from a psychiatric inpatient hospital. Patrick (Bradley Cooper), who is trying to reconnect with his ex-wife and manage bipolar disorder, meets Tiffany (Jennifer Lawrence), who is struggling with depression following the death of her husband. Throughout the film, issues relating to stigma, establishing a therapeutic relationship, and how individuals suffering from mental illness may mutually support each other are dealt with.

VIEWING POINTS: As part of Patrick's release, he is mandated to continue meeting with a therapist. Think of this in relation to the Transitional Discharge Model discussed earlier. How is it similar and how is it different? Others often stigmatize Patrick and Tiffany. Can you identify where this happens and how such treatment might be avoided? Reflect on the fact that many other characters seem to have undiagnosed mental illnesses (such as obsessive-compulsive disorder and anxiety). How do the characters help and hurt each other as they deal with the challenges of mental illness?

The Psychiatric–Mental Health Nursing Process

Mary Ann Boyd

KEYCONCEPTS

- assessment
- clinical Judgment
- mental status examination
- outcomes
- recovery-oriented nursing interventions
- spirituality

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Define the recovery-oriented nursing process in psychiatric–mental health nursing.
2. Conduct a psychiatric–mental health nursing assessment.
3. Apply clinical judgment in recognizing, analyzing, and prioritizing assessment data.
4. Develop recovery-oriented goals in collaboration with the patient.
5. Apply recovery-oriented psychiatric–mental health nursing interventions by supporting patient strengths and addressing mental health problems and mental disorders.
6. Collaborate with the patient in evaluating outcomes.

KEY TERMS

- Affect

INTRODUCTION

The psychiatric–mental health nursing process is approached from the perspectives of wellness and strength as well as mental health problems. The process is guided by recovery principles and practices (see Chapters 1 and 9). In this text, the nursing process is built by recognizing and analyzing patient’s data and cues, prioritizing problems or concerns, generating a plan in collaboration with the patient, using clinical judgment, applying interventions, and evaluating outcomes. This chapter describes some, but not all, of the commonly applied interventions. The nursing process targeting specific psychiatric disorders and emotional problems is discussed in later chapters.

RECOVERY-ORIENTED PSYCHIATRIC–MENTAL HEALTH NURSING ASSESSMENT

Assessment is the collection and interpretation of information related to health, wellness, strengths, functional status, and human responses to mental health problems. Assessment involves recognizing cues and analyzing the information for significance to the patient's health status. These data are collected within a collaborative relationship with the person seeking nursing care.

Assessment is not an isolated activity. Rather, it is a systematic and ongoing process that occurs throughout the nurse's care of the patient. The psychiatric–mental health nursing assessment ([Box 11.1](#)) is a basic guide to collecting assessment data. Assessment information is entered into the patient's written or computerized record, which may be presented in several different formats, including forms, checklists, narratives, and problem-oriented notes.

KEYCONCEPTS **Assessment** is the deliberate and systematic collection and interpretation of information or data to determine current and past health, wellness, strengths, functional status, and mental health problems, both actual and potential.

Assessment begins with the first contact with the patient when a collaborative relationship is initiated. Legal consent must be given by the patient, and the nurse must follow the Health Insurance Portability and Accountability Act of 1996 guidelines (see Chapter 4). The patient must develop a sense of trust before they will be comfortable revealing intimate life details. It is of paramount importance that the nurse have a healthy knowledge of themselves as well ([Box 11.2](#)). The nurse's own biases and values, which may be different from those of the patient, can influence the nurse's interpretation of assessment data. A careful self-assessment helps the nurse interpret the data objectively.

Patient Interviews

An assessment interview usually involves direct questions to obtain facts, clarify perceptions, validate observations, interpret the meanings of facts, or compare information. The specific questions may take different forms. The nurse must clearly state the purpose of the interview and, if necessary, modify the interview

process, so that both the patient and nurse agree on its purpose. The nurse may choose to use open- or closed-ended questions. Open-ended questions are most helpful when beginning the interview because they allow the nurse to observe how the patient responds verbally and nonverbally. They also convey caring and interest in the person's well-being, which helps to establish rapport. Nurses should use closed-ended questions when they need specific information. For example, "How old are you?" asks for specific information about the patient's age. These types of questions limit the individual's response but often serve as good follow-up questions for clarification of thoughts or feelings expressed.

Questions such as "How did you come to this clinic today?" allow patients to describe their experience in their own way. Some patients may answer this question concretely by saying, "I took a taxi" or "I came by car." Others may address this question by responding, "My family thought I should come, so they brought me" or "Well, I got up this morning ... I took a shower, got dressed ... and then, well you know, it's difficult sometimes to decide." Each of these answers helps the nurse assess the patient's thinking process as well as evaluate the content of the response.

Clarification is extremely important during the assessment process. Words do not have the same meaning to all people. Education, language, culture, history, and experience may influence the meaning of words. Sometimes, simple and direct questioning provides clarification. In other situations, the nurse may clarify by providing a specific example for a more global thought the patient is trying to express. For example, a patient may say, "Things have been so strange since the children left." The nurse may respond with, "Sometimes, parents feel sad and empty when their children leave home. They don't know what to do with their time." Frequently summarizing what has been said allows the patient the opportunity to correct the nurse's interpretation. For example, verbalizing a sequence of events that the patient has reported may help to identify omissions or inconsistencies. Restating information or reflecting feelings that the patient has described also allows opportunity for clarification. It is essential that nurses understand exactly what patients are attempting to communicate before beginning to intervene. [Box 11.3](#) provides a summary of other behaviors that enhance the effectiveness of an assessment interview.

Many psychiatric symptoms are beyond a patient's awareness. Family members, friends, and other health care professionals are important sources of information. Before seeking information from others, the nurse must obtain permission from the patient. The nurse needs to provide the patient with a clear

explanation of why the information is needed and how it will be used. The nurse should explain that the strength-based assessment will include questions about wellness and strengths as well as mental health problems because these are all related to well-being.

Assessment of Trauma

During the assessment, the nurse should listen for any clues of trauma including physical, emotional, or social events. If a person has been hospitalized for any mental health problem, it is important to understand the meaning of the experience to the individual. Psychiatric hospitalizations can be traumatic and can contribute to posttraumatic stress disorders. Any abuse or mistreatment should be identified in the assessment (see Chapters 23 and 29).

BOX 11.1

Psychiatric–Mental Health Nursing Assessment

I. Major reason for seeking help _____

II. Initial information
 Name _____
 Age _____ Marital status _____ Gender _____ Ethnic identification _____

III. Present and past health status _____ (Include ht., wt., BMI)

Summary of strengths and wellness related to physical health

	Normal	Treated	Untreated
Physical functions: System review	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Elimination	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Activity/exercise	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Sleep	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Appetite and nutrition	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Hydration	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Sexuality	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Self-care	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Neurological status (head trauma, movement disorder)	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Existing physical illnesses	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Medications (prescription and over the counter)	Dosage	Side effects	Frequency
Significant laboratory tests	Values	Normal range	

IV. Mental health problems
 Major concerns regarding mental health problem _____
 Major loss/change in past year: No _____ Yes _____
 Fear of violence: No _____ Yes _____
 Past abuse or trauma: No _____ Yes _____
 Strategies for managing problems/disorder _____

V. Mental status examination
 General observations (appearance, psychomotor activity, attitude) _____
 Orientation (time, place, person) _____
 Mood, affect, emotions _____
 Speech (verbal ability, speed, use of words correctly) _____
 Thought processes (tangential, logic, repetition, rhyming of words, loose connections, disorganized) _____
 Cognition and intellectual performance _____
 Attention and concentration _____
 Abstract reasoning and comprehension _____
 Memory (recall, short-term, recent, and remote) _____
 Judgment and insight _____

VI. Significant behaviors (psychomotor, agitation, aggression, withdrawn) _____

VII. Self-concept (body image, self-esteem, personal identity) _____

VIII. Stress and coping patterns _____

IX. Risk assessment
 Suicide: High _____ Low _____ Assault/homicide: High _____ Low _____
 Suicidal thoughts or ideation: No _____ Yes _____
 Current thoughts of harming self _____
 Intention _____
 Behavior _____
 Lethality _____
 Assault/homicide thoughts: No _____ Yes _____
 What do you do when angry with a stranger? _____
 What do you do when angry with family or partner? _____
 Have you ever hit or pushed anyone? No _____ Yes _____
 Have you ever been arrested for assault? No _____ Yes _____
 Current thoughts of harming others _____

X. Functional status
 Changes in functioning (work, school, home) _____

XI. Social systems
 Family assessment
 Family members _____
 Members important to patient _____
 Decision makers, family roles, supportive members _____
 Cultural assessment
 Cultural group _____
 Cultural group's view of health and mental illness _____
 What cultural rules do you try to live by? _____
 Important cultural foods _____
 Community resources _____

XII. Spiritual assessment

XIII. Economic status

XIV. Legal status

XV. Quality of life

XVI. Spiritual Care Assessment

XVII. SUMMARY OF PSYCHOSOCIAL STRENGTHS:
 Summary of significant data that can be used in prioritizing patient needs.
 SIGNATURE/TITLE _____ Date _____

BOX 11.2

Self-Concept Awareness

Self-awareness is important in any interaction. To understand a patient's self-concept, the nurse must be aware of their own self-concept. By answering these questions, nurses can evaluate self-concept components and increase their self-understanding. The more comfortable nurses are with themselves, the more effective they can be in each patient interaction.

BODY IMAGE

- How do I feel about my body?
- How important is my physical appearance?
- How does my body measure up to my ideal body? (How would I like to appear?)
- What is positive about my body?
- What would I like to change about my body?
- How does my body image affect my self-esteem?

SELF-ESTEEM

- When do I feel confident and good about myself?
- When do I feel unimportant?
- What do I do when I feel good about myself? (Call friends, socialize?)
- What do I do when I have negative feelings about myself? (Withdraw, dress poorly?)
- When do I make negative statements?
- Am I able to correct my negative self-statements?

PERSONAL IDENTITY

- How do I describe myself?
- What three adjectives describe who I am?
- Do I identify with a particular cultural group, family role, or place of residence?
- What would I like to have on my tombstone?

Virtual Mental Health Assessment

There is an emerging trend to use virtual health technology (i.e., telehealth) in assessment and treatment of mental health problems. The need for social distancing due to the COVID-19 pandemic escalated the use of digital tools. Limiting face-to-face contact is especially important for vulnerable populations such as the older adult. Virtual health care increases access to care in those areas where there is a shortage of services.

There are two types of telehealth used in mental health. **Synchronous communication**, real-time telehealth interactions between nurse and patient, and asynchronous or stored-and-forward telehealth. In asynchronous communication,

clinical information is transmitted from patient to clinician or clinician to patient and stored for review at a later point. **Asynchronous communication** can include emails, text message, and video recordings. Mobile technologies, cell phones, and other devices are becoming increasingly popular and useful throughout the care process. Consistent with patient-centered care, use of mobile health applications (*mHealth*) is useful for history taking, interviewing, assessment, and treatment as well as clinician support for decision-making and up-to-date treatment (Tsanas et al., 2021).

BOX 11.3

Assessment Interview Behaviors

The following behaviors carried out by the nurse will enhance the effectiveness of the assessment interview:

- *Exhibiting empathy*—to show empathy to the patient, the nurse uses phrases such as “That must have been upsetting for you” or “I can understand your hurt feelings.”
- *Giving recognition*—the nurse gives recognition by listening actively: verbally encouraging the patient to continue and nonverbally presenting an open, interested demeanor.
- *Demonstrating acceptance*—note that acceptance does not mean agreement or nonagreement with the patient but is a neutral stance that allows the patient to continue.
- *Restating*—the nurse tries to clarify what the patient is trying to say by restating it.
- *Reflecting*—the nurse presents the patient’s last statement as a question. This gives the patient a chance to expand on the information.
- *Focusing*—the nurse attempts to bring the conversation back to the questions at hand when the patient goes off on a tangent.
- *Using open-ended questions*—general questions give the patient a chance to speak freely.
- *Presenting reality*—the nurse presents reality when the patient makes unrealistic or exaggerated statements.
- *Making observations*—the nurse says aloud what patient behaviors are observed to give the patient a chance to speak to those behaviors. For example, the nurse may say, “I notice you are twisting your fingers; are you nervous about something?”

It is important that nurses assess their patients’ use of virtual devices (Smahel et al., 2019). These devices can be incorporated into their care based on patient preference, skill, and need. There are some risks related to using virtual technology, such as privacy breaches, unnecessary self-disclosure, and cyberbullying.

Assessment of Physical Health

Many mental disorders produce physical symptoms, such as the lack of appetite and weight loss associated with depression. Physical health can also affect mental health and illness, producing a recurrence or increase in symptoms. Many physical disorders may present first with symptoms considered to be psychiatric. For example, hypothyroidism often presents with feelings of lethargy, decreased concentration, and depressed mood. For these reasons, physical health information about the patient is always considered.

Current and Past Health Status

Beginning with a history of the patient's general medical condition, the nurse should consider the following:

- Availability of, frequency of, and most recent medical evaluation, including test results
- Past hospitalizations and surgical procedures
- Vision and hearing impairments
- Cardiac problems, including cerebrovascular accidents (strokes), myocardial infarctions (heart attacks), and childhood illnesses
- Respiratory problems, particularly those that result in a lack of oxygen to the brain
- Neurologic problems, particularly head injuries, seizure disorders, or any losses of consciousness
- Endocrine disorders, particularly unstable diabetes or thyroid or adrenal dysfunction
- Immune disorders, particularly human immunodeficiency virus (HIV) and autoimmune disorders
- Use, exposure, abuse, or dependence on substances, including alcohol, tobacco, prescription drugs, illicit drugs, and herbal preparations

Physical Examination

Body Systems Review

After the nurse obtains historical information, they should examine physiologic systems to evaluate the patient's current physical condition. The psychiatric nurse should pay special attention to various systems that treatment may affect. For example, if a patient is being treated with antihypertensive medication, the dosage may need to be adjusted if an antipsychotic medication is prescribed. If a patient is overweight or has diabetes, some psychiatric medications can affect these conditions. Patients with compromised immune function (HIV, cancer) may experience mood alterations.

Neurologic Status

Particular attention is paid to recent head trauma; episodes of hypertension; and changes in personality, speech, or the ability to handle activities of daily living (ADLs). Cranial nerve dysfunction, reflexes, muscle strength, and balance are included in a thorough assessment. The nurse routinely assesses and documents movement disorders using such tools as the Abnormal Involuntary Movement Scales (see Chapter 24 and Appendix B).

Laboratory Results

The nurse reviews and documents any available laboratory data, especially any abnormalities. Hepatic, renal, or urinary abnormalities are particularly important to document because these systems metabolize or excrete many psychiatric medications. In addition, the nurse notes abnormal white blood cell and electrolyte levels. Laboratory data are especially important, particularly if the nurse is the only person in the mental health team who has a “medical” background ([Table 11.1](#)).

Table 11.1: SELECTED HEMATOLOGIC MEASURES AND THEIR RELEVANCE TO PSYCHIATRIC DISORDERS

Test	Possible Results	Possible Cause or Meaning
------	------------------	---------------------------

Complete Blood Count

Leukocyte (WBC) count	Leukopenia— decrease in leukocytes (WBCs) Agranulocytosis— decrease in number of granulocytic leukocytes Leukocytosis— increase in leukocyte count above normal limits	May be produced by phenothiazine, clozapine, carbamazepine Lithium causes a benign mild to moderate increase (11,000–17,000/mcL) NMS can be associated with increases of 15,000–30,000/mm ³ in about 40% of cases
WBC differential	“Shift to the left”—from segmented neutrophils to band forms	Shift often suggests a bacterial infection but has been reported in about 40% of cases of NMS
RBC count	Polycythemia— increased RBCs	Primary form—true polycythemia caused by several disease states Secondary form—compensation for decreased oxygenation, as in chronic pulmonary disease Blood is more viscous, and the patient should not become dehydrated
Hct	Decreased RBCs Elevations Decreased Hct	Decrease may be related to some types of anemia, which requires further evaluation Elevation may be caused by dehydration Anemia may be associated with a wide range of mental status changes, including asthenia, depression, and psychosis 20% of women of childbearing age in the United States have iron-deficiency anemia
Hb	Decreased	Another indicator of anemia; further evaluation of source requires review of erythrocyte indices

Erythrocyte indices, such as RDW	Elevated RDW	Finding suggests a combined anemia, as in that from chronic alcoholism, resulting from both vitamin B ₁₂ and folate acid deficiencies and iron deficiency Oral contraceptives also decrease vitamin B ₁₂
----------------------------------	--------------	---

Other Hematologic Measures

Vitamin B ₁₂	Deficiency	Neuropsychiatric symptoms, such as psychosis, paranoia, fatigue, agitation, marked personality change, dementia, and delirium may develop
Folate	Deficiency	The use of alcohol, phenytoin, oral contraceptives, and estrogens may be responsible
Platelet count	Thrombocytopenia—decreased platelet count	Some psychiatric medications, such as carbamazepine, phenothiazine, or clozapine, or other nonpsychiatric medications may cause thrombocytopenia Several medical conditions are other causes

Serum Electrolytes

Sodium	Hyponatremia—low serum sodium	Significant mental status changes may ensue. Condition is associated with Addison disease, the SIADH, and polydipsia (water intoxication) as well as carbamazepine use
Potassium	Hypokalemia—low serum potassium	Produces weakness, fatigue, ECG changes; paralytic ileus and muscle paresis may develop Common in individuals with bulimic behavior or psychogenic vomiting and use or abuse of diuretics; laxative abuse may contribute; can be life threatening
Chloride	Elevation	Chloride tends to increase to compensate for lower bicarbonate
	Decrease	Binging–purging behavior and repeated vomiting may be causes
Bicarbonate	Elevation	Causes may be binging and purging in eating

	Decrease	disorders, excessive use of laxatives, or psychogenic vomiting Decrease may develop in some patients with hyperventilation syndrome and panic disorder
Renal Function Tests		
BUN	Elevation	Increase is associated with mental status changes, lethargy, and delirium Cause may be dehydration Potential toxicity of medications cleared via the kidney, such as lithium and amantadine, may increase
Serum creatinine	Elevation	Level usually does not become elevated until about 50% of nephrons in the kidney are damaged
Serum Enzymes		
Amylase	Elevation	Level appears to increase after bingeing and purging behavior in eating disorders and declines when these behaviors stop
ALT—formerly SGPT	ALT > AST Elevation	Disparity is common in acute forms of viral and drug-induced hepatic dysfunction Mild elevations are common with use of sodium valproate
AST—formerly SGOT	AST > ALT	Severe elevations in chronic forms of liver disease and postmyocardial infarction may develop
CPK	Elevations of the isoenzyme related to muscle tissue	Muscle tissue injury is the cause Level is elevated in NMS Level is also elevated by repeated intramuscular injections (e.g., antipsychotics)
Thyroid Function		
Serum triiodothyronine (T ₃)	Decrease	Hypothyroidism and nonthyroid illness cause decrease Individuals with depression may convert less T ₄ to T ₃ peripherally but not out of the normal range

		Medications such as lithium and sodium valproate may suppress thyroid function, but clinical significance is unknown
	Elevations	Hyperthyroidism, T ₃ , and toxicosis may produce mood changes, anxiety, and symptoms of mania
Serum thyroxine (T ₄)	Elevations	Hyperthyroidism is a cause
TSH or thyrotropin	Elevations	Hypothyroidism—symptoms may appear very much like those of depression except for additional physical signs of cold intolerance, dry skin, hair loss, bradycardia, and so on
	Decrease	Lithium—may also cause elevations Considered nondiagnostic—may be hyperthyroidism, pituitary hypothyroidism, or even euthyroid status

Note. ALT = alanine aminotransferase; AST = aspartate aminotransferase; BUN = blood urea nitrogen; CPK = creatine phosphokinase; ECG = electrocardiogram; Hb = hemoglobin; Hct = hematocrit; NMS = neuroleptic malignant syndrome; RBC = Red blood cell; RDW = red cell distribution width; SIADH = syndrome of inappropriate secretion of antidiuretic hormone; SGPT = serum glutamic pyruvic transaminase; SGOT = serum glutamic oxaloacetic transaminase; TSH = thyroid-stimulating hormone; WBC = white blood cell.

Physical Functions

Elimination

The nurse should inquire about and document the patient's daily urinary and bowel habits. Various medications can affect bladder and bowel functioning, so a baseline must be noted. For example, diarrhea and frequency of urination can

occur with the use of lithium carbonate. Anticholinergic effects of antipsychotic medication can cause constipation and urinary hesitancy or retention.

Activity and Exercise

The patient's daily methods and levels of activity and exercise must be queried and documented. Activities are important interventions, and baseline information is needed to determine what the patient already enjoys or dislikes and whether they are getting sufficient exercise or adequate recreation. A patient may have altered activity or exercise in response to medication or therapies. In addition, many psychiatric medications cause weight gain, and nurses need to develop interventions that assist the patient in increasing activities to counteract the weight gain.

Sleep

Changes in sleep patterns often reflect changes in a patient's emotions and are symptoms of disorders. If the patient responds positively to a question about changes in sleep patterns, it is important to clarify just what those changes are. For example, "difficulty falling asleep" means different things to different people. For a person who usually falls right to sleep, it could mean that it takes 10 extra minutes to fall asleep. For a person who normally takes 35 minutes to fall asleep, it could mean that it takes 90 minutes to do so.

Appetite and Nutrition

Changes in appetite and nutritional intake are assessed and documented because they can indicate changes in moods or relapse. For example, a patient who is depressed may not notice hunger or even that they do not have the energy to prepare food. Others may handle stressful emotions through eating more than usual. This information also provides valuable clues to possible eating disorders and problems with body image.

Obesity is one of the major health problems of many Americans, but it is particularly problematic for persons with psychiatric disorders. Many of the medications are associated with weight gain. A baseline body mass index should be determined as treatment is initiated.

Hydration

Gaining perspective on how much fluid patients normally drink and how much they are drinking now provides important data. Some medications can cause retention of fluids, and others can cause diuresis; thus, the patient's current fluid status must be understood.

Sexuality

Questioning a patient on issues involving sexuality requires comfort with one's own sexuality. Changes in sexual activity as well as comfort with sexual orientation are important to assess. Issues involving sexual orientation that are unsettled in a patient or between a patient and family member may cause anxiety, shame, or discomfort. It is necessary to explore how comfortable the patient is with their sexuality and sexual functioning. These questions should be asked in a matter of fact but gentle and nonjudgmental manner. Initiating the topic of sexuality may begin with a question such as "Are you sexually active?" Birth control medications may also alter mood.

Self-Care

Self-care is the ability to perform ADLs successfully. Often, a patient's ability to care for themselves or carry out ADLs, such as washing and dressing, are indicative of their psychological state. For example, a depressed patient may not have the energy to change into clean clothes. This information may also help the nurse to determine actual or potential obstacles to a patient's compliance with a treatment plan.

Pharmacologic Assessment

The review of systems serves as a baseline from which the nurse may judge whether the initiation of a medication exacerbates symptoms or causes new ones to develop. It is important to determine which medications the patient takes now or has taken in the past. These include over-the-counter, herbal, or nonprescription medications as well as prescribed medications. This assessment

is important for reasons other than serving as a baseline. It helps target possible drug interactions, determines whether the patient has already used medications that are being considered, and identifies whether medications may be causing psychiatric symptoms.

Strengths and Wellness Assessment

During the assessment, the nurse should identify areas of strength and wellness including **physical well-being** or positive sleep patterns, healthy diet, or motivation to engage in healthy behaviors. Does the patient recognize the need for physical activity, diet, and nutrition? Recognition of this wellness dimension can help motivate the individual to improve these behaviors.

Psychological Assessment

Psychological concerns are the traditional emphasis of the psychiatric–mental health nursing assessment. By definition, mental disorders and emotional problems are manifested through psychological symptoms related to mental status, moods, thoughts, behaviors, and interpersonal relationships. Psychological strengths, psychological growth, and development are important parts of this assessment as well as wellness and emotional and intellectual well-being.

Mental Health Problems

Individual concerns regarding a mental health problem or its consequences are included in the mental health assessment. A mental disorder, like any other illness, affects patients and families in many ways. It is safe to say that a mental illness changes a person's life, and the nurse should identify what the changes are and their meaning to the patient and family members. Many patients experience specific fears, such as losing their job, family, or safety. Because the nurse will be supporting coping strategies, it is important to identify current strategies or behaviors the patient uses. A simple question such as “How do you

deal with your voices when you are with other people?” may initiate a discussion about responses to the mental disorder or emotional problem.

Mental Status Examination

The mental status examination establishes a baseline, provides a snapshot of where the patient is at a moment, and creates a written record. Areas of assessment include general observations, orientation, mood and affect, speech, thought processes, and cognition. [Box 11.4](#) provides a narrative note of the results from a patient’s mental status examination.

BOX 11.4

Narrative Mental Status Examination Note

M.J. is a 65-year-old widowed man who is slightly disheveled. He is cooperative with the interviewer and judged to be an adequate historian. His mood and affect are depressed and anxious. He becomes tearful throughout the interview when speaking about his wife. His flow of thought is hesitant but coherent when he is speaking about his wife. He is oriented to time, place, and person. He shows good recent and remote memory. He can recall several items given to him by the interviewer. He shows poor insight and judgment regarding his sadness since the loss of his wife. He repeatedly says, “Mary wouldn’t want me to be sad. She would want me to continue with my life.”

KEYCONCEPTS The **mental status examination** is an organized systematic approach to assessment of an individual’s current psychiatric condition.

General Observations

At the beginning of the interview, the nurse should record their initial impressions of the patient. These general observations include the patient’s appearance, affect, psychomotor activity, and overall behavior. How is the patient dressed? Is the dress appropriate for the weather and setting? What is the patient’s affect (emotional expression)? What behaviors is the patient displaying? For example, the same nurse assessed two male patients with depression. At the beginning of the mental status examination, the differences between these two men were very clear. The nurse described the first patient as “a large, well-dressed man who is agitated and appears angry, shifts in his seat,

and does not maintain eye contact. He interrupts often in the initial explanation of mental status.” The nurse described the other patient as a “small, unshaven, disheveled man with a strong body odor who appears withdrawn. He shuffles as he walks, speaks very softly, appears sad, and avoids direct eye contact.”

Orientation

The nurse can determine the patient’s orientation by asking the date, time, and current location of the interview setting. If a patient knows the year but not the exact date, the interviewer can ask the season. A person’s orientation tells the nurse the extent of confusion. If a patient does not know the year or the place of the interview, they are exhibiting considerable confusion.

Mood and Affect

Mood refers to the prominent, sustained, overall emotions that the person expresses and exhibits. Mood may be sustained for days or weeks, or it may fluctuate during the course of a day. For example, some patients with depression have a diurnal variation in their mood. They experience their lowest mood in the morning, but as the day progresses, their depressed mood lifts and they feel somewhat better in the evening. Terms used to describe mood include **euthymic** (normal), **euphoric** (elated), **labile** (changeable), and **dysphoric** (depressed, disquieted, and restless).

Affect refers to the person’s capacity to vary outward emotional expression. Affect fluctuates with thought content and can be observed in facial expressions, vocal fluctuations, and gestures. During the assessment, the patient may exhibit anger, frustration, irritation, apathy, and helplessness while their overall mood remains unchanged.

Affect can be described in terms of range, intensity, appropriateness, and stability. Range can be full or restricted. An individual who expresses several different emotions consistent with the stated feelings and content being expressed is described as having a *full range* of affect that is congruent with the situation. An individual who expresses few emotions has a restricted affect. For example, a patient could be describing the recent tragic death of a loved one in a monotone with little expression. In determining whether this response is normal, the nurse compares the patient’s emotional response with the cultural norm for that particular response. *Intensity* can be increased, flat, or blunted. The nurse

determines whether the emotional response is *appropriate* for the situation. For example, an inappropriate response is shown by a patient who has an extreme reaction to the death of the victims of the September 11 tragedy, as if the victims were personal friends. Another patient said that his life stopped when the World Trade Center towers came down. He could not eat or sleep for weeks afterward. *Stability* can be mobile (normal) or labile. If a patient reports feeling happy one minute and reduced to tears the next, the person probably has an unstable mood. During the interview, the nurse should look for rapid mood changes that indicate lability of mood. A patient who exhibits intense, frequently shifting emotional extremes has a labile affect.

Speech

Speech provides clues about thoughts, emotional patterns, and cognitive organization. Speech may be pressured, fast, slow, or fragmented. Speech patterns reflect the patient's thought patterns, which can be logical or illogical. To check the patient's comprehension, the nurse can show a patient an object (e.g., pen, watch) and ask the person to name them. During conversation, the nurse assesses the fluency and quality of the patient's speech. The nurse listens for repetition or rhyming of words.

Thought Processes

The nurse assesses the patient for rapid change of ideas; inability or taking a long time to get to the point; loose or no connections among ideas or words; rhyming or repetition of words, questions, or phrases; or use of unheard-of words. Any of these observations indicates abnormal thought patterns. The content of what the patient says is also important. What thought is the patient expressing? The nurse listens for unusual and unlikely stories, fears, or behaviors, for example, "The FBI is tracking me" or "I am afraid to leave my house."

Cognition and Intellectual Performance

The nurse can assess for **intellectual well-being** by determining the extent that the patient recognizes their creative abilities and is able to learn new knowledge and skills. To assess the patient's cognition, that is, the ability to think and know,

the nurse uses memory, calculation, and reasoning tests to identify specific areas of impairment. The cognitive areas include (1) attention and concentration, (2) abstract reasoning and comprehension, (3) memory, and (4) insight and judgment.

Attention and Concentration

To test attention and concentration, the nurse asks the patient, without pencil or paper, to start with 100 and subtract 7 until reaching 65 or to start with 20 and subtract 3. The nurse must decide which is most appropriate for the patient considering education and understanding. Subtracting 3 from 20 is the easier of the two tasks. Asking a patient to spell “world” backward is also useful in determining attention and concentration.

Abstract Reasoning and Comprehension

To test abstract reasoning and comprehension, the nurse gives the patient a proverb to interpret. Examples include “People in glass houses shouldn’t throw stones,” “A rolling stone gathers no moss,” and “A penny saved is a penny earned.”

Recall, Short-Term, Recent, and Remote Memory

There are four spheres of memory to check: recall, or immediate, memory; short-term memory; recent memory; and long-term, or remote, memory. To check immediate and short-term memory, the nurse gives the patient three unrelated words to remember and asks them to recite them right after telling them and at 5- and 15-minute intervals during the interview. To test recent memory, the nurse may question about a holiday or world event within the past few months. The nurse tests long-term or remote memory by asking about events years ago. If they are personal events and the answers seem incorrect, the nurse may check them with a family member.

Insight and Clinical Judgment

Insight and judgment are related concepts that involve the ability to examine thoughts, conceptualize facts, solve problems, think abstractly, and possess self-

awareness. **Insight** is a person's awareness of their own thoughts and feelings and ability to compare them with the thoughts and feelings of others. It involves an awareness of how others view one's behavior and its meaning. For example, many patients do not believe that they have mental illness. They may have delusions and hallucinations or be hospitalized for bizarre and sometimes dangerous behavior, but they are completely unaware that their behavior is unusual or abnormal. During an interview, a patient may adamantly proclaim that nothing is wrong or that they do not have a mental illness. Even if a problem is recognized, the patient may lack insight regarding issues related to care.

Clinical judgment is the ability to reach a logical decision about a situation and to choose a course of action after examining and analyzing various possibilities. Throughout the interview, the nurse evaluates the patient's ability to make logical decisions. For example, some patients may continually choose partners who are abusive. The nurse could logically conclude that these patients have poor judgment in selecting partners. Another way to examine a patient's judgment is to give a simple scenario and ask the person to identify the best response. An example of such a scenario is asking, "What would you do if you found a bag of money outside a bank on a busy street?" If the patient responds with "Run with it," their judgment is questionable.

Behavior

Throughout the assessment, the nurse observes any behavior that may have significance in understanding the patient's response or symptoms of the mental disorder or emotional problem. For example, a depressed patient may be tearful throughout the session, whereas an anxious patient may twist or pull their hair, shift in the chair, or be unable to maintain eye contact. The nurse may find that whenever a topic is addressed, the patient's behavior changes. The nurse needs to relate patterned behaviors to significant events by connecting behaviors with the assessment data. For example, a patient may change jobs frequently, causing family distress and financial problems. Exploration of the events leading up to job changes may elicit important information regarding the patient's ability to solve problems.

Self-Concept

Self-concept, which develops over a lifetime, represents the total beliefs about three interrelated dimensions of the self: body image, self-esteem, and personal identity. The importance of each of these dimensions varies among individuals. For some, beliefs about themselves are strongly tied to body image; for others, personal identity is most important. Still others develop personal identity from what others have told them over the years. The nurse carrying out an assessment must keep in mind that self-concept and its components are dynamic and variable. For example, a woman may have a consistent self-concept until her first pregnancy. At that time, the many physiologic changes of pregnancy may cause her body image to change. She may be comfortable and enjoy the “glow of pregnancy,” or she may feel like a “bloated cow.” Suddenly, her body image is the most important part of her self-concept, and how she handles it can increase or decrease her self-esteem or sense of personal identity. Thus, all the components are tied together, and each one affects the others.

Self-concept is assessed through eliciting patients’ thoughts about themselves, their ability to navigate in the world, and their nonverbal behaviors. A disheveled sloppy physical appearance outside cultural norms is an indication of poor self-concept. Negative self-statements, such as, “I could never do that,” “I have no control over my life,” and “I’m so stupid,” reveal poor views of self. The nurse’s own self-concept can shape the nurse’s view of the patient. For example, a nurse who is self-confident and feels inwardly scornful of a patient who lacks such confidence may intimidate the patient through unconscious, judgmental behaviors or inconsiderate comments.

A useful approach to measuring self-concept is asking the patient to draw a self-portrait. For many patients, drawing is much easier than writing and serves as an excellent technique for monitoring changes. Interpretation of self-concept from drawings focuses on size, color, level of detail, pressure, line quality, symmetry, and placement. Low self-esteem is expressed by small size, lack of color variation, and sparse details in the drawing. Powerlessness and feelings of inadequacy are expressed through a lack of a head, a mouth, arms, feet, or in the drawing. A lack of symmetry (placement of figure parts or entire drawings off center) represents feelings of insecurity and inadequacy. As self-esteem builds, size increases, color tends to become more varied and brighter, and more details appear. [Figure 11.1](#) shows a self-portrait of a patient at the beginning of

treatment for depression and another drawn 3 months later.

Body Image

Body image represents a person's beliefs and attitudes about their body and includes such dimensions as size (large or small) and attractiveness (pretty or ugly). People who are satisfied with their body have a more positive body image than those who are not satisfied. Generally, women attach more importance to their body image than do men and may even define themselves in terms of their body.

Patients express body image beliefs through statements about their bodies. Statements such as "I feel so ugly," "I'm so fat," and "No one will want to have sex with me" express negative body images. Nonverbal behaviors indicating problems with body image include avoiding looking at or touching a body part; hiding the body in oversized clothing; or bandaging a particularly sensitive area, such as a mole on the face. Cultural differences must be considered when evaluating behavior related to body image. For example, the expectation of some cultures is that women and girls will keep their bodies completely covered and wear loose-fitting garments.

Figure 11.1: *Left:* Self-portrait of a 52-year-old woman at first group session following discharge from hospital for treatment of depression. *Right:* Self-portrait after 3 months of weekly group interventions.

NCLEXNOTE Be prepared to assess reactions to a body image change (e.g., loss of vision, paralysis, colostomy, amputation).

Self-Esteem

Self-esteem is the person's attitude about the self. Self-esteem differs from body image because it concerns satisfaction with one's overall self. People who feel good about themselves are more likely to have the confidence to try new health behaviors. They are also less likely to be depressed. Negative self-esteem statements include "I'm a worthless person" and "I never do anything right."

Personal Identity

Personal identity is knowing "who I am." Every life experience and interaction contribute to knowing oneself better. Personal identity allows people to establish boundaries and understand personal strengths and limitations. In some psychiatric disorders, individuals cannot separate themselves from others, which shows that their personal identity is not strongly developed. A problem with personal identity is difficult to assess. Statements such as "I'm just like my mother, and she was always in trouble," "I become whatever my current boyfriend wants me to be," and "I can't make a decision unless I check it out first" are all statements that require further exploration into the person's view of self.

Stress and Coping Patterns

Everyone has stress (see Chapter 19). One of the dimensions of wellness is **emotional well-being** or the ability to cope with stress through skills and strategies. Sometimes, the experience of stress contributes to the development of mental disorders. Identification of major stresses in a patient's life helps the nurse understand the person and support the use of successful coping behaviors in the future. The nurse should explore how the patient deals with stress and identify successful coping mechanisms to encourage their use.

NCLEXNOTE Every assessment should focus on stress and coping patterns.

Identifying how a patient copes with stress can be used as a basis of care in all nursing situations. Include content from Chapter 19 when studying these concepts.

Risk Assessment

Risk factors are characteristics, conditions, situations, or events that increase the patient's vulnerability to threats to safety or well-being. Throughout this text, the sections concerning risk factors focus on the following:

- Risks to the patient's safety
- Risks for developing psychiatric disorders
- Risks for increasing, or exacerbating, symptoms and impairment in an individual who already has a psychiatric disorder

Consideration of risk factors involving patient safety should be included in each assessment. Examples of these risks include the risk for suicide and violence toward others or the risk for events, such as falling, seizures, allergic reactions, or elopement (unauthorized absence from health care facility). Nurses assess factors on a priority basis. For example, threats of violence or suicide take priority.

Suicide Screening

Every mental health nursing assessment should include a suicide screening. During the assessment, the nurse needs to listen closely to whether the patient describes or mentions thinking about self-harm. If the patient does not openly express ideas of self-harm, it is necessary to ask straightforward questions related to suicide.

The Columbia Suicide Severity Rating Scale (C-SSRS) is a commonly used, evidence-based measure used to identify and assess individuals at risk for suicide (Posner et al., 2011). This instrument measures severity of suicidal ideation, intensity of ideation, suicidal behavior, and lethality. It is appropriate for use over the telephone or in telehealth. C-SSRS screening toolkits are available for specific settings such as health care, correctional facilities, primary care, and police officers. All the screening tools consist of six questions. The C-SSRS for health care providers is a good place for nurses to learn the questions and how to respond (see [Box 11.5](#)).

Two questions should be included in the screening. "Have you wished you were dead or wished you could go to sleep and not wake up?" and "Have you actually had any thoughts about killing yourself?" If the answer is "no" to both questions, the nurse should ask one more. "Have you done anything, started to

do anything, or prepared to do anything to end your life?” If the answer is “no” to the third question, the nurse can assume that the person most likely is not suicidal.

If the answer is “yes” to any of these three questions, the nurse should ask the following three questions. “Have you thought about how you might do this?” “Have you had any intention of acting on these thoughts of killing yourself, as opposed to you have the thoughts but you would definitely would not act on them?” and “Have you done anything, started to do anything, or prepared to do anything to end your life?” If the answer is “yes” to any of these questions, the nurse should seek a referral to advanced practice nurse, psychologist, or other mental health clinicians trained to complete a comprehensive assessment. The nurse should notify the supervisor and clearly document the patient responses and nursing follow-up. The nurse should not leave the patient alone and should explore the details of the intention and behavior. If a nurse and patient are not face to face, but on the telephone or other virtual means, the nurse should keep the patient talking and follow agency policy. The National Suicide Prevention Lifeline (1-800-273-8255) is a resource that can provide support and direction to the nurse as well as the patient.

To assess patient ability to coping suicidal thoughts, the nurse can ask the patient to identify strategies that were used in resisting suicidal urges and actions. For example, one patient reported calling a family member to talk when the suicidal urges were strong. The nurse can encourage the patient to use these strategies in the future. This information will be helpful in the development of a safety plan (see Chapter 22).

Assaultive or Homicidal Ideation

When assessing a patient, the nurse also needs to listen carefully to any delusions or hallucinations that the patient shares. If the patient gives any indication that they must or are being told to harm someone, the nurse must first think of self-safety and institute assaultive precautions as indicated by the facility protocols. General questions to ascertain assaultive or homicidal ideation follow:

BOX 11.5

The Columbia Suicide Severity Rating Scale

	Past Month
1) Have you wished you were dead or wished you could go to sleep and not wake up?	
2) Have you actually had any thoughts about killing yourself?	
If YES to 2, answer questions 3, 4, 5 and 6 If NO to 2, go directly to question 6	
3) Have you thought about how you might do this?	
4) Have you had any intention of acting on these thoughts of killing yourself, as opposed to you have the thoughts but you definitely would not act on them?	High Risk
5) Have you started to work out or worked out the details of how to kill yourself? Do you intend to carry out this plan?	High Risk
Always Ask Question 6	Life-time Past 3 Months
6) Have you done anything, started to do anything, or prepared to do anything to end your life? <i>Examples: Collected pills, obtained a gun, gave away valuables, wrote a will or suicide note, held a gun but changed your mind, cut yourself, tried to hang yourself, etc.</i>	High Risk

Any **YES** indicates that someone should seek a behavioral health referral.
However, if the answer to **4, 5 or 6** is **YES**, seek immediate help: go to the emergency room, call 1-800-273-8255, text 741741 or call 911 and STAY WITH THEM until they can be evaluated.

- Do you intend to harm someone? If yes, who?
- Do you have a plan? If yes, what are the details of the plan?
- Do you have the means to carry out the plan? (If the plan requires a weapon, is it readily available?)

Social Assessment

The nurse collects information on the patient's social support and networks. The nurse elicits cues about interactions with others in the family and community (work, church, or other organizations); parents and their marital relationship; place in birth order; and relationships with spouse, siblings, and children. The nurse also assesses work and education history and community activities. The nurse observes how the patient relates to any family or friends who may be in attendance. This component of the assessment helps the nurse anticipate how the patient may get along with other patients in an inpatient setting. It also allows the nurse to plan for any anticipated difficulties.

Functional Status

An important aspect of the assessment is determining the functioning of the patient (i.e., Is an adult working and living independently? Is a student attending classes?). How the patient copes with strangers and those with whom they do not get along is also important information.

Social Systems

A significant component of the patient's life involves the social systems in which they may be enmeshed. **Social well-being** involves developing a sense of connection and a well-developed support system. The social systems to examine include the family, the culture to which the patient belongs, and the community in which they live.

Family Assessment

How the patient fits in with and relates to their family is important to know. General questions to ask include the following:

- Who do you consider family?
- How important to you is your family?
- How does your family make decisions?
- What are the roles in your family, and who fills them?
- Where do you fit in your family?
- With whom in your family do you get along best?
- With whom in your family do you have the most conflict?
- Who in your family is supportive of you?

Cultural Assessment

Culture can profoundly affect a person's worldview (see Chapter 3). Culture helps a person frame beliefs about life, death, health and illness, and roles and relationships. During cultural assessment, the nurse must consider factors that influence the manifestations of the current mental disorder. For example, a patient mentions "speaking in tongues." The nurse may identify this experience as a hallucination when, in fact, the patient was having a religious experience common within some branches of Christianity. In this instance, knowing and understanding such religious practices will prevent a misinterpretation of the symptoms.

The nurse can elicit important cultural information by asking the following questions:

- To what cultural group do you belong?
- Were you raised in an ethnic community?
- How do you define health?
- How do you define illness?
- How do you define good and evil?
- What do you do to get better when you are physically ill? Mentally ill?
- Whom do you see for help when you are physically ill? Mentally ill?
- By what cultural rules or taboos do you try to live?
- Do you eat special foods?

Community Support and Resources

Many patients are connected to community resources, and the nurse needs to assess what they are and the patterns of usage. For example, a patient who is homeless may know of a church where they can sleep but may go there only on cold nights. Or a patient may go to the community center daily for lunch to be with other people. Examining the environment is a part of the individual's assessment. **Environmental well-being** involves living in pleasant, stimulating environments that support a healthy lifestyle.

Occupational Status

Occupational well-being involves personal satisfaction and enrichment derived from one's work. The nurse should document the occupation the patient is now in as well as a history of jobs. If the patient has changed jobs frequently, the nurse should ask about the reasons. Perhaps the patient has faced such problems as an inability to focus on the job at hand or to get along with others. If so, such issues require further exploration.

Economic Status

Finances are very private for many people; thus, the nurse must ask questions about economic status carefully. However, **financial well-being** is satisfaction with present and future situations. What the nurse needs to ascertain is not specific dollar amounts but whether the patient feels stressed by finances and has enough for basic needs.

Legal Status

Because of laws governing people with mental illness, ascertaining the patient's correct age, marital status, and any legal guardianship is important. The nurse may need to check the patient's medical records for this information.

Quality of Life

The patient's perspective on quality of life means how the patient rates their life. Does a patient feel his life is poor because he cannot purchase everything he wants? Does another patient feel blessed because the sun is shining today? Listening carefully to the patient's discussion of their life and how they measure the quality of that life provides important information about self-concept, coping skills, desires, and dreams.

Psychosocial Strengths and Wellness Assessment

Throughout the assessment, the nurse should be able to identify areas of strength and wellness. A description of these areas should be validated with the patient and documented in the person's record.

Spiritual Assessment

KEYCONCEPTS Spirituality “is a way of being in the world in which a person feels a sense of connectedness to self, others, and/or a higher power or nature: a sense of meaning in life; and transcendence beyond self, everyday living, and suffering” (Weathers et al., 2015, 93).

Several studies show that spirituality and religion are important in coping with mental disorders through providing hope, comfort, and meaning of life and serve as a resource for coping with symptoms, substance abuse, and protection against suicide (Das et al., 2018; Paul et al., 2018). Nurses must be clear about their own spirituality to be sure it does not interfere with assessment of the patient's spirituality. Nurses also need to work within their area of competence and recognize the importance of referring patients to a health care chaplain or other spiritual care support.

The purpose of a **spiritual care assessment**, which is often the responsibility of the nurse, is to identify specific spiritual care needs and to formulate a care plan. A nursing spiritual assessment is usually included in the general nursing assessment, even when there are chaplains available (Timmins & Caldeira, 2017). The Joint Commission requires that spiritual care assessment and spiritual

care delivery be directed to the patient or the patient's family but does not identify specific disciplines of the personnel who will conduct the assessment (The Joint Commission, 2020).

The spiritual assessment is based on an individual's needs, which are discovered within an open, trusting dialogue. It is important that the nurse does not self-disclose personal values and beliefs during the assessment. The following questions can serve to initiate the assessment:

- How important is spirituality and/or religion in your life and coping with an illness?
- Are you involved in a religious or faith community?
- Would you like to address these issues in your mental health care?
- If yes, with whom would you like to address these issues?

Spiritual assessment questions need to correspond to the patient's readiness to discuss this topic. Patients and clinicians agree that it may take time for the patient to feel comfortable and ready to discuss spirituality. It is essential that questions are asked that focus on a patient's strengths. For example, asking the question "Was there a time in your life where you felt great peace and joy and maybe not so stressed out?" is less judgmental than the question "What were your sources of deep meaning, peace, joy, and strength during your times of stress?" The latter statement has an implied expectation that there should be sources (religious, spiritual) that exist.

Examples of questions that could help patients examine past or current spiritually related strengths and resources include the following (Gomi et al., 2014):

- Was there a time in your life when you really felt at peace?
- What do you do to get through the tough times (pray, meditate, visit nature, family)?
- When do you feel most positive about yourself?
- What brings inspiration to your life?

Questions that can help the individual connect to spiritual goals to recovery goals (if that is a goal of the person) include the following (Gomi et al., 2014):

- What helps you feel good or hopeful about your life?
- Is spirituality something you want to connect with in your recovery?
- Based on what you said, how would you say your spirituality could support your recovery?

KEYCONCEPTS Clinical judgment is an iterative decision-making process that uses nursing knowledge to observe and assess presenting situations; identify a prioritized client concern; and generate the best possible evidence-based solutions to deliver safe client care.

USING CLINICAL JUDGMENT

One of the challenges of conducting an assessment is keeping track of important health and mental health cues and differentiating significant signs and symptoms from those that may not be relevant to the patient's area of concern. In a collaborative process, the patient and nurse prioritize the patient's concerns and generate solutions. There will be times when the patient and nurse are at odds about the top priority. For example, a nurse may identify treatment of psychosis as a priority and the patient may want a place to stay. Using evidence that supports the patient's request, the nurse generates a plan to find housing before the patient will consider medications. In another instance, a patient has a credible suicide plan, and the nurse insists that safety is the top priority and is a life-or-death situation.

With experience, the nurse can cluster the assessment data to identify two or three immediate health or mental health problem issues related to promotion of health and well-being, prevention of illness, reduction of risks, or treat health care problems.

DEVELOPING RECOVERY GOALS AND OUTCOMES

Mutually agreed-upon goals flow from the prioritization of needs and provide guidance in determining appropriate interventions. Initial goals are determined and then are monitored and evaluated throughout the care process.

Measuring outcomes not only demonstrates clinical effectiveness but also helps to promote rational clinical decision-making and is reflective of the nursing interventions.

KEYCONCEPTS Outcomes are health experiences and evaluations reported by the patient or observed by the nurse related to symptoms, functioning, well-being, health perceptions, and satisfaction with care that can be attributed to nursing care at a given point in time (Broderick et al., 2013).

An expected outcome is concise, stated in few words and in neutral terms (Table 11.2).

Expected outcomes are developed mutually with the patient. Nurses are accountable for documenting patient outcomes, nursing interventions, and any changes in health status or care plan or both. Outcomes can be expressed in terms of the patient's actual responses (no longer reports hearing voices) or the health or mental health changes after implementation of nursing interventions.

Table 11.2: EXAMPLE OF OUTCOMES

Issue	Outcome	Intervention
Social isolation	Social involvement Indicators: a. Interact with other patients b. Attend group meetings	Using a contract format, explain role and responsibility of patients

RECOVERY-ORIENTED NURSING INTERVENTIONS

Recovery-oriented patient/nurse-initiated treatment is an autonomous action within the scope of nursing practice. It can also be physician-initiated treatment through an order written in the patient's record. In both instances, the nurse is held to a standard of nursing care.

KEYCONCEPTS Recovery-oriented nursing interventions are nursing actions or treatment, selected based on clinical judgment and mutual decision-making with the patient, that are designed to achieve patient, family, or community outcomes. Interventions can be direct or indirect and can target specific symptoms, health needs, and strengths (see Box 11.6).

There are several nursing interventions systems, including the Nursing Interventions Classification (Butcher et al., 2019), the Clinical Care Classification system (Saba, 2017), and the Omaha nursing model (Martin, 2005; Martin & Kessler, 2017). All these systems are recognized by the American Nurses Association. In this text, the *Psychiatric-Mental Health*

Nursing: Scope and Standards of Practice guides the use of interventions (American Nurses Association [ANA], American Psychiatric Nurses Association [APNA], & International Society of Psychiatric-Mental Health Nurses [ISPN], 2014). Some are adapted from classification systems and others from the psychiatric–mental health nursing literature.

Physical Interventions

Biologic interventions focus on physical functioning and are directed toward the patient’s self-care, activities and exercise, sleep, nutrition, relaxation, hydration, and thermoregulation as well as pain management and medication management.

Promotion of Self-Care Activities

Many patients with psychiatric–mental health problems can manage ADLs or self-care activities such as bathing, dressing appropriately, selecting adequate nutrition, and sleeping regularly. Others cannot manage such self-care activities, either because of their symptoms or because of the side effects of medications.

BOX 11.6

Recovery-Oriented Intervention in Inpatient Unit

Molin, J., Hällgren Graneheim, U., Ringnér, A., & Lindgren, B. M. (2020). *Time Together as an arena for mental health nursing-staff experiences of introducing and participating in a nursing intervention in psychiatric inpatient care*. *International Journal of Mental Health Nursing*, 10.1111/inm.12759. Advance online publication. <https://doi.org/10.1111/inm.12759>

THE QUESTION: What are the experiences of the staff when a recovery-oriented intervention, Time Together (TT), is implemented in inpatient mental health unit?

METHODS: In this qualitative study, staff were interviewed and data analyzed after implementing TT, a regularly scheduled time the patients every day for a minimum of one hour. In the relationship-building intervention, patients and staff would engage in joint activities, that is, board games, and bingo, preferably chosen by the patients. Staff ($N = 17$) were asked to talk about what TT meant to them and how they had experienced introducing and participating in TT. The interviews lasted between 16 and 55 minutes. Interviews were recorded. Data were analyzed using a qualitative content analysis.

FINDINGS: Staff prepared for the introduction of the intervention by laying a framework for success by making joint decisions, providing structure and taking responsibility, and being flexible. Even though the implementation led to feeling burdened, they found that TT fostered relationship between patients and staff.

IMPLICATIONS FOR NURSING: Nurses can easily be consumed with nonpatient responsibilities leading to dissatisfaction. To support the development of therapeutic relationships, nurses must advocate for interventions that are critical components of recovery-oriented practice.

In the inpatient setting, the psychiatric nurse structures the patient's activities, so that basic self-care activities are completed. During acute phases of psychiatric disorders, the inability to attend to basic self-care tasks, such as getting dressed, is very common. Thus, the ability to complete personal hygiene activities (e.g., dental care, grooming) is monitored, and patients are assisted in completing such activities. In a psychiatric facility, patients are encouraged and expected to develop independence in completing these basic self-care activities. In the community, monitoring these basic self-care activities is always a part of the nursing visit or clinic appointment.

Activity and Exercise Interventions

In some psychiatric disorders (e.g., schizophrenia), people become sedentary and appear to lack the motivation to complete ADLs. This lack of motivation is part of the disorder and requires nursing intervention. In addition, side effects of medication often include sedation and lethargy. Encouraging regular activity and exercise can improve general well-being and physical health. In some instances, exercise behavior becomes an abnormal focus of attention, as may be observed in some patients with anorexia nervosa.

When assuming the responsibility of direct care provider, the nurse can help patients identify realistic activities and exercise goals. As leader or manager of a psychiatric unit, the nurse can influence ward routine. Alternatively, the nurse can delegate activity and exercise interventions to nurses' aides. Some institutions have other professionals (e.g., recreational therapists) available for the implementation of exercise programs. As a case manager, the nurse should consider the activity needs of individuals when coordinating care.

Sleep Interventions

Many psychiatric disorders and medications are associated with sleep disturbances. Sleep is also disrupted in patients with dementia; such patients may have difficulty falling asleep or may frequently awaken during the night. In dementia of the Alzheimer type, individuals may reverse their sleeping patterns by napping during the day and staying awake at night.

Nonpharmacologic interventions are always used first because of the side-effect risks associated with the use of sedatives and hypnotics (see Chapter 12). Sleep interventions to communicate to patients include the following:

- Go to bed only when tired or sleepy.
- Establish a consistent bedtime routine.
- Avoid stimulating foods, beverages, or medications.
- Avoid naps in the late afternoon or evening.
- Eat lightly before retiring and limit fluid intake.
- Use your bed only for sleep or intimacy.
- Avoid emotional stimulation before bedtime.
- Use behavioral and relaxation techniques.
- Limit distractions.

Nutrition Interventions

Psychiatric disorders and medication side effects can affect eating behaviors. For varying reasons, some patients eat too little, but others eat too much. For instance, homeless patients with mental illnesses have difficulty maintaining adequate nutrition because of their deprived lifestyle. Substance abuse also interferes with maintaining adequate nutrition, either through stimulation or suppression of appetite or through neglecting nutrition because of drug-seeking behavior. Thus, nutrition interventions should be specific and relevant to the individual's circumstances and mental health. In addition, recommended daily nutritional allowances are important in the promotion of physical and mental health, and nurses should consider them when planning care.

Some psychiatric symptoms involve changes in perceptions of food, appetite, and eating habits. If a patient believes that food is poisonous, they may eat

sparingly or not at all. Interventions are then necessary to address the suspiciousness as well as to encourage adequate intake of recommended daily allowances. Allowing patients to examine foods, participate in preparations, and test the safety of the meal by eating slowly or after everyone else may be necessary. For patients who are paranoid, it is sometimes helpful to serve prepackaged foods.

Relaxation Interventions

Relaxation promotes comfort, reduces anxiety, alleviates stress, eases pain, and prevents aggression. It can diminish the effects of hallucinations and delusions. The many different relaxation techniques used as mental health interventions range from simple deep breathing to biofeedback to hypnosis. Although some techniques, such as biofeedback, require additional training and, in some instances, certification, nurses can easily apply simple relaxation, distraction, and imagery techniques.

Simple relaxation techniques encourage and elicit relaxation to decrease undesirable signs and symptoms. **Distraction** is the purposeful focusing of attention away from undesirable sensations, and **guided imagery** is the purposeful use of imagination to achieve relaxation or direct attention away from undesirable sensations (Box 11.7).

Relaxation techniques that involve physical touch (e.g., back rubs) usually are not used for people with mental disorders. Touching and massaging usually are not appropriate, especially for those who have a history of physical or sexual abuse. Such patients may find touching too stimulating or misinterpret it as being sexual or aggressive.

Hydration Interventions

Assessing fluid status and monitoring fluid intake and output are often important interventions. Overhydration or underhydration can be a symptom of a disorder. For example, some patients with psychotic disorders experience chronic fluid imbalance. Many psychiatric medications affect fluid and electrolyte balance (see Chapter 12). For example, when taking lithium carbonate, patients must

have adequate fluid intake and pay special attention to testing serum sodium levels. Interventions that help patients understand the relationship of medications to fluid and electrolyte balance are important in their overall care.

BOX 11.7

Relaxation Techniques: Descriptions and Implementation

RELAXED BREATHING

The goal of this exercise is to slow down your breathing, especially your exhaling.

Steps

1. Choose a word that you associate with relaxation, such as calm, relax, or peaceful.
2. Inhale through your nose and exhale slowly through your mouth. Take normal breaths, not deep ones.
3. While you exhale, say the relaxing word you have chosen. Say it very slowly, like this: “c-a-a-a-a-a-l-m” or “r-e-e-e-l-a-a-x.”
4. Pause after exhaling before taking your next breath. If it is not too distracting, count to 4 before inhaling each new breath.
5. Repeat the entire sequence 10 to 15 times.

MUSCLE RELAXATION

The goal of this technique is to gently stretch your muscles to reduce stiffness and tension. The exercises start at your head and work down to your feet. You can do these exercises while sitting in a chair.

Steps

1. *Neck rolls.* Drop your head to one side. Gently roll it around in a wide circle. Repeat three to five times. Then reverse directions, and gently roll your head in a wide circle the other way. Repeat three to five times.
2. *Shoulder shrugs.* Lift both shoulders in a shrugging motion. Try to touch your ears with your shoulders. Let your shoulders drop down after each shrug. Repeat three to five times.
3. *Overhead arm stretches.* Raise both arms straight above your head. Interlace your fingers, like you are making a basket, with your palms facing down (toward the floor). Stretch your arms toward the ceiling. Then, keeping your fingers interlaced, rotate your palms to face upward (toward the ceiling). Stretch toward the ceiling. Repeat three to five times. If it is not comfortable to do this step with your arms overhead, try it with your arms reaching out in front of you.
4. *Knee raises.* Reach down and grab your right knee with one or both hands. Pull your knee up toward your chest (as close to your chest as is comfortable). Hold your knee there for a few seconds, before returning your foot to the floor. Reach down and grab your left knee with one or both hands and bring it up toward your chest. Hold it there for a few seconds. Repeat the sequence three to five times.
5. *Foot and ankle rolls.* Lift your feet and stretch your legs out. Rotate your ankles and feet, three to five times in one direction, then three to five times in the other direction.

Reprinted from Substance Abuse and Mental Health Services Administration. (2009). Illness management and recovery: Practitioner guides and handouts. HHS Pub. No. SMA-09-4462, Center for Mental Health Services, Substance Abuse and Mental Health Services Administration, U.S. Department of Health and

Thermoregulation Interventions

Many psychiatric disorders can disturb the body's normal temperature regulation. Thus, patients cannot sense temperature increases or decreases and consequently cannot protect themselves from extremes of hot or cold. This problem is especially difficult for people who are homeless or live outside the protected environments of institutions and boarding homes. In addition, many psychiatric medications affect the ability to regulate body temperature.

Interventions include educating patients about the problem of thermoregulation, identifying potential extremes in temperatures, and developing strategies to protect the patient from the adverse effects of temperature changes. For example, reminding patients to wear coats and sweaters in the winter or to wear loose, lightweight garments in the summer may prevent frostbite or heat exhaustion, respectively.

Pain Management

Psychiatric nurses are more likely to provide care to patients experiencing chronic pain than acute pain. However, a single intervention is seldom successful for relieving chronic pain. In some instances, pain is managed by medication; in other instances, nonpharmacologic strategies, such as simple relaxation techniques, distraction, or imagery, are used. Indeed, relaxation is one of the most widely used cognitive and behavioral approaches to pain. Education, stress management techniques, hypnosis, and biofeedback are also used in pain management. Physical agents include heat and cold therapy, exercise, and transcutaneous nerve stimulation.

The key to managing pain is identifying how it disrupts the patient's personal, social, professional, and family life. Education focusing on the pain, use of medications for treatment, and development of cognitive skills are important pain management components. In some cases, redefining treatment success as improvement in functioning, rather than alleviation of pain, may be necessary. The interaction between stress and pain is important; that is, increased stress leads to increased pain. Patients can better manage their pain when stress is

reduced.

Medication Management

The psychiatric–mental health nurse uses many medication management interventions to help patients maintain therapeutic regimens. Medication management involves more than the actual administration of medications. Nurses also assess medication effectiveness and side effects and consider drug–drug interactions. Monitoring the amount of lethal prescription medication is particularly important. For example, check if patients have old prescriptions of tricyclic antidepressants in their medicine cabinets. Treatment with psychopharmacologic agents can be lengthy because of the chronic nature of many disorders; many patients remain on medication regimens for years, never becoming free of medication. Thus, medication education is an ongoing intervention that requires careful documentation. Medication follow-up may include home visits as well as telephone calls.

Psychological Interventions

A major emphasis in psychiatric–mental health nursing is the psychological domain: emotion, behavior, and cognition. The basis of nursing care is establishing a therapeutic relationship with the patient. Because the therapeutic relationship was extensively discussed in Chapter 10, it is not covered in this chapter. This section does cover cognitive interventions, counseling, conflict resolution, bibliotherapy, reminiscence, behavior therapy, psychoeducation, health teaching, and spiritual interventions. Chapter 7 presents the theoretic basis for many of these interventions.

Cognitive Interventions

Evidence-based cognitive interventions are used in a variety of practice settings (inpatient and outpatient). The knowledge and skills inherent in cognitively based interventions have been extensively studied, and their effectiveness has

been demonstrated for a variety of psychiatric disorders, especially depression (see Chapter 25) and anxiety and related disorders (see Chapters 26 – 28).

Cognitive interventions are based on the concept of cognition. **Cognition** can be defined as an internal process of perception, memory, and judgment through which an understanding of self and the world is developed.

Cognitive interventions aim to change or reframe an individual's automatic thought patterns that have developed over time and that interfere with the individual's ability to function optimally. The skills and techniques developed based on cognitive theory result in a new view of self and the environment.

Counseling Interventions

Counseling interventions are interactions between a nurse and a patient, family, or group experiencing immediate or ongoing difficulties related to their health or well-being. Counseling is usually short term and focuses on stabilizing symptoms, supporting personal recovery goals, improving coping abilities, reinforcing healthy behaviors, fostering positive interactions, or preventing illness and disability. Counseling strategies are discussed throughout the text. Psychotherapy, which differs from counseling, is generally a long-term approach aimed at improving or helping patients regain previous health status and functional abilities. Mental health specialists, such as advanced practice nurses, use psychotherapy.

Conflict Resolution and Cultural Brokering

Conflict resolution is a process of helping an individual or family identify a problem underling a disagreement or dispute and developing alternative possibilities for solving the conflict (Weitzman & Weitzman, 2014). Conflict can be positive if individuals see the problem as solvable and providing an opportunity for growth and interpersonal understanding. The nurse may be in the position of teaching family members how to resolve their own conflicts positively. Key elements of any conflict resolution process are collaboration, motivation to seek a solution, and the ability to see the other person's point of view. Conflict resolution strategies are commonly taught to adolescents who are

experiencing cyberbullying and to adults in marital or romantic relationships (Courtain & Glowacz, 2019; Garaigordobil & Martínez-Valderrey, 2018; Özgüc & Tanriverdi et al., 2018). Nurses are often in leadership positions and use conflict resolution skills to settle employee disputes.

At times, patients who are politically and economically powerless find themselves in conflict with the health care system. Differences in cultural values and languages among patients and health care organizations contribute to feelings of powerlessness. For example, immigrant families, migrant farm workers, people who are homeless, and people who need to make informed decisions under stressful conditions may be unable to navigate the health care system. The nurse can help to resolve such conflicts through **cultural brokering**, the act of bridging, linking, or mediating messages, instructions, and belief systems between groups of people of differing cultural systems to reduce conflict or produce change (Lazarevic, 2017).

For the “nurse as broker” to be effective, the nurse establishes and maintains a sense of connectedness or relationship with the patient. In turn, the nurse also establishes and cultivates networks with other health care facilities and resources. Cultural sensitivity enables the nurse to be aware of and sensitive to the needs of patients from a variety of cultures. Cultural competence is necessary for the brokering process to be effective.

Bibliotherapy and Social Media

Bibliotherapy, sometimes referred to as bibliocounseling, is the reading of selected written materials to express feelings or gain insight under the guidance of a health care provider. The provider assigns and discusses with the patient a book, story, or article. The provider makes the assignment because they believe that the patient can receive therapeutic benefit from the reading. (It is assumed that the provider who assigned the reading has also read it.) The provider needs to consider the patient’s reading level before making an assignment. If a patient has limited reading ability, the provider should not use bibliotherapy.

Literary works serve as a projective screen through which people see themselves in the story. Literature can help patients identify with characters and vicariously experience their reality. The use of bibliotherapy has been shown to improve depression when used with cognitive behavioral therapy (Yuan et al., 2018). It can also expose patients to situations that they have not personally

experienced—the vicarious experience allows growth in self-knowledge and compassion (Escovar et al., 2019). Bibliotherapy can also support recovery in inpatient units through reading books written in first person (Eisen et al., 2018). Through reading, patients can enrich their lives in the following ways:

- *Catharsis*: expression of feelings stimulated by parallel experiences
- *Problem-solving*: development of solutions to problems in the literature from practical ideas about problem-solving
- *Insight*: increased self-awareness and understanding as the reader explores personal meaning from what is read
- *Anxiety reduction*: use of self-help written materials that can reduce concerns about a diagnosed problem and treatment

Using the internet can be helpful to patients, but it also has drawbacks. Some websites can help patients gain insight into their problems through acquiring new knowledge and interacting with others in the privacy of their own surroundings. Web materials and chat groups are variable in quality and accuracy. Nurses should carefully evaluate the quality of the website.

Reminiscence

Reminiscence, the thinking about or relating of past experiences, is used as a nursing intervention to enhance life review in older patients. Reminiscence encourages patients, either in individual or in group settings, to discuss their past and review their lives. Through reminiscence, individuals can identify past coping strategies that can support them in current stressful situations. Patients can also use reminiscence to maintain self-esteem, stimulate thinking, and support the natural healing process of life review. Activities that facilitate reminiscence include writing an account of past events, making an audio recording and playing it back, explaining pictures in old family albums, drawing a family tree, and writing to old friends.

Behavior Therapy

Behavior therapy interventions focus on reinforcing or promoting desirable behaviors or altering undesirable ones. The basic premise is that because most

behaviors are learned, new functional behaviors can also be learned. Behaviors—not internal psychic processes—are the targets of the interventions. The models of behavioral theorists serve as a basis for these interventions (see Chapter 7).

Behavior Modification

Behavior modification is a specific, systematized behavior therapy technique that can be applied to individuals, groups, or systems. The aim of behavior modification is to reinforce desired behaviors and extinguish undesired ones. Desired behavior is rewarded to increase the likelihood that patients will repeat it, and over time, replace the problematic behavior with it. Behavior modification is used for various problematic behaviors, such as dysfunctional eating, addictions, anger management, and impulse control and often is used in the care of children and adolescents.

Token Economy

Used in inpatient settings and in group homes, a **token economy** applies behavior modification techniques to multiple behaviors. In a token economy, patients are rewarded with tokens for selected desired behaviors. They can use these tokens to purchase meals, leave the unit, watch television, or wear street clothes. In less restrictive environments, patients use tokens to purchase additional privileges, such as attending social events.

Token economy systems have been especially effective in reinforcing positive behaviors in people who are developmentally disabled or have severe and persistent mental illnesses. There is good evidence that the use of token economy for behavior and symptom management is effective in adults who are hospitalized, but there is little evidence to support transfer of the new behaviors outside the inpatient settings (Glowacki et al., 2016). The strategy has been expanded to treatment programs for children (Hickey et al., 2018) and cocaine addiction (Pirnia et al., 2016).

Psychoeducation

Psychoeducation uses educational strategies to teach patients the skills they lack because of a psychiatric disorder. The goal of psychoeducation is a change in knowledge and behavior. Nurses use psychoeducation to meet the educational needs of patients by adapting teaching strategies to their disorder-related deficits (Box 11.8). As patients gain skills, functioning improves. Some patients may need to learn how to maintain their morning hygiene. Others may need to understand their illness and cope with hearing voices that others do not hear.

Specific psychoeducation techniques are based on adult learning principles, such as beginning at the point where the learner is currently and building on their current experiences. Thus, the nurse assesses the patient's current skills and readiness to learn. From there, the nurse individualizes a teaching plan for each patient. They can conduct such teaching in a one-to-one situation or in a group format.

Psychoeducation is a continuous process of assessing, setting goals, developing learning activities, and evaluating for changes in knowledge and behavior. Nurses use it with individuals, groups, families, and communities. Psychoeducation serves as a basis for psychosocial rehabilitation, a service delivery approach for those with severe and persistent mental illness (see Chapter 24).

BOX 11.8

Psychoeducation Program for Parents of Children with Attention-Deficit/Hyperactivity Disorder (ADHD)

Gümüş, F., Ergün, G., & Dikeç, G. (2020). Effect of psychoeducation on stress in parents of children with attention-deficit/hyperactivity disorder: A randomized controlled study. *Journal of Psychosocial Nursing and Mental Health Services*, 58(7), 34–41. <https://doi.org/10.3928/02793695-20200506-01>

THE QUESTION: Does a psychoeducation program reduce the stress of parents of children with attention-deficit/hyperactivity disorder?

METHODS: A randomized controlled study was performed using pre-/posttest scores in experimental and control groups ($N = 172$). There was no significant difference between mean pretest scores of parents in the experimental and control groups on the Caregiver Stress Scale. The intervention consisted of four psychoeducation sessions for the experimental group, and the control group parents attended two meetings with no intervention.

FINDINGS: Psychoeducation decreased parents' stress immediately and 6 months after compared to the control group.

IMPLICATIONS FOR NURSING: Psychiatric–mental health nurses can use psychoeducation programs

to support families of children with attention-deficit/hyperactivity disorder to reduce their stress levels.

NCLEXNOTE Apply knowledge from social sciences to help patients manage responses to psychiatric disorders and emotional problems.

Health Teaching

Health teaching is one of the standards of care for the psychiatric nurse. Teaching methods should be appropriate to the patient's development level, learning needs, readiness, ability to learn, language preference, and culture. Based on principles of learning, health teaching involves transmitting new information to the patient and providing constructive feedback and positive rewards, practice sessions, homework, and experimental learning. Health teaching is the integration of principles of teaching and learning with the knowledge of health and illness (Fig. 11.2).

Thus, in health teaching, the psychiatric nurse attends to potential health care problems other than mental disorders and emotional problems. For example, if a person has diabetes mellitus and is taking insulin, the nurse provides health care teaching related to diabetes and the interaction of this problem with the mental disorder.

Spiritual Interventions

Spiritual care is based on an assessment of the patient's spiritual needs. Some interventions require actions such as listening, requesting a chaplain's presence, or providing readings; other interventions involve use of personal abilities and characteristics such as the use of the therapeutic relationship in supporting patient well-being. A nonjudgmental relationship and just "being with" (not doing for) the patient are key spiritual interventions. To assist people in spiritual distress, the nurse should know and understand the beliefs and practices of various spiritual groups. **Spiritual support**, assisting patients to feel balance and connection within their relationships, involves listening to expressions of loneliness, using empathy, and providing patients with desired spiritual articles (Caldeira & Timmons, 2017).

Social Interventions

The social domain includes the individual's environment and its effect on their responses to mental disorders and distress. Interventions within the social domain are geared toward couples, families, friends, and large and small social groups, with special attention given to ethnicity and community interactions. In some instances, nurses design interventions that affect a patient's environment, such as helping a family member decide to admit a loved one to a long-term care facility. In other instances, the nurse modifies the environment to promote positive behaviors. Group interventions are discussed in Chapter 14.

Social Behavior and Privilege Systems in Inpatient Units

In psychiatric units, unrelated strangers who have problems interacting live together in close quarters, sometimes with two to four people sharing bedrooms and bathrooms. For this reason, most psychiatric units develop a list of behavioral expectations called unit rules that staff members post and explain to patients upon admittance. Their purpose is to facilitate a comfortable and safe environment; they have little to do with the patients' reasons for admission. Getting up at certain times, showering before breakfast, making the bed, and not visiting others' rooms are typical expectations. It is usually the nurse manager who oversees the operation of the unit and implementation of privilege systems.

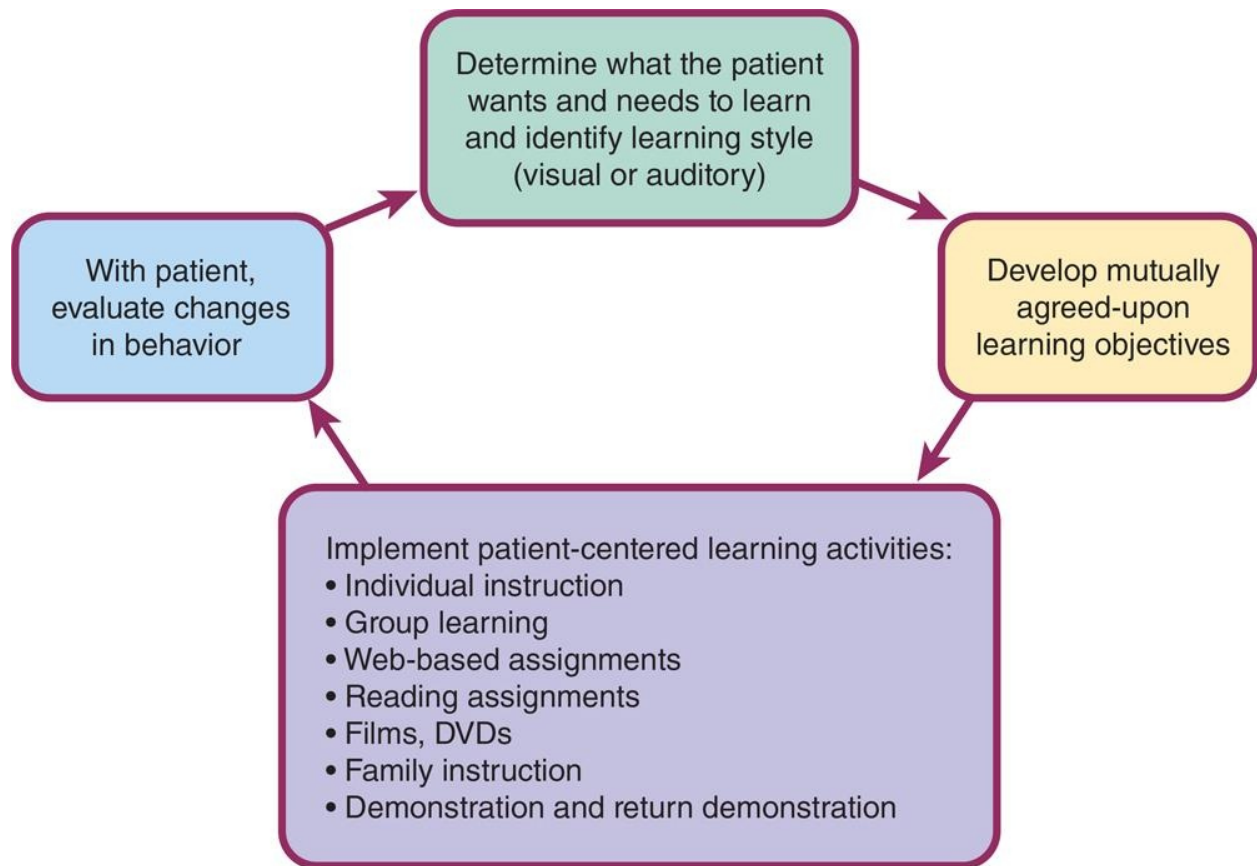

Figure 11.2: Teaching evaluation model.

Most psychiatric facilities use a privilege system to protect patients and to reinforce unit rules and other appropriate behavior (also see the previous section discussing token economies). The more appropriate the behavior, the more privileges of freedom the person has. Privileges are based on the assessment of a patient's risk to harm themselves or others and ability to follow treatment regimens. For example, a patient with few privileges may be required to stay on the unit and eat only with other patients. A patient with full privileges may have freedom to leave the unit and go outside the hospital and into the community for short periods.

Milieu Therapy

Milieu therapy provides a stable and coherent social organization to facilitate an individual's treatment. (The terms *milieu therapy* and *therapeutic environment* are often used interchangeably.) In **milieu therapy**, the design of the physical

surroundings, structure of patient activities, and promotion of a stable social structure and cultural setting enhance the setting's therapeutic potential. A therapeutic milieu facilitates patient interactions and promotes personal growth. Milieu therapy is the responsibility of the nurse in collaboration with the patient and other health care providers. The key concepts of milieu therapy include containment, validation, structured interaction, and open communication.

Containment

Containment is the process of providing safety and security and involves the patient's access to food and shelter. In a well-contained milieu, patients feel safe from their illnesses and protected against social stigma. The physical surroundings are also important in this process and should be clean and comfortable, with special attention paid to promoting a noninstitutionalized environment. Pictures on walls, comfortable furniture, and soothing colors help patients relax. Most facilities encourage patients and nursing staff to wear street clothes, which help decrease the formalized nature of hospital settings and promote nurse–patient relationships.

Therapeutic milieus emphasize patient involvement in treatment decisions and operation of the unit; nurses should encourage freedom of movement within the contained environment. Patients participate in maintaining the quality of the physical surroundings, assuming responsibility for making their own beds, attending to their own belongings, and keeping an acceptable living area. Families are viewed as a part of the patient's life, and ties are maintained. In most inpatient settings, specific times are set for family interaction, education, and treatment. Family involvement is often a criterion for admission for treatment, and the involvement may include regular family attendance at therapy sessions.

Validation

In a therapeutic environment, **validation** is another process that affirms patient individuality. Staff–patient interactions should constantly reaffirm the patient's humanity and human rights. All interaction a staff member initiates with a patient should reflect their respect for that patient. Patients must believe that staff members truly like and respect them.

Structured Interaction

One of the most interesting milieu concepts is **structured interaction**, which is purposeful interaction that allows patients to interact with others in a useful way. For instance, the daily community meeting provides structure to explain unit rules and consequences of violations. Ideally, patients who either are elected or volunteer for the responsibility assume leadership for these meetings. In the meeting, the group discusses behavioral expectations, such as making beds daily, appropriate dress, and rules for leaving the unit. Usually, there are other rules, such as no fighting or name calling.

In some instances, the treatment team assigns structured interactions to specific patients as part of their treatment. Specific attitudes or approaches are directed toward individual patients who benefit from a particular type of interaction. Nurses consistently assume indulgence, flexibility, passive or active friendliness, matter-of-fact attitude, casualness, watchfulness, or kind firmness when interacting with specific patients. For example, if a patient is known to overreact and dramatize events, the staff may provide a matter-of-fact attitude when the patient engages in dramatic behavior.

Open Communication

In **open communication**, the staff and patient willingly share information. Staff members invite patient self-disclosure within the support of a nurse–patient relationship. In addition, they provide a model of effective communication when interacting with one another as well as with patients. They arrange an environment to facilitate optimal interaction and resocialization. Support, attention, praise, and reassurance given to patients improve self-esteem and increase confidence. Patient education is also a part of this support, as are directions to foster coping skills.

Milieu Therapy in Different Settings

Milieu therapy is applied in various settings. In long-term care settings, the therapeutic milieu becomes essential because patients may reside there for months or years. These patients typically have schizophrenia or developmental disabilities. Structure in daily living is important to the successful functioning of the individuals and the overall group but must be applied within the context of

individual needs. For example, if a patient cannot get up one morning in time to complete assigned tasks (e.g., showering or making a bed) because of a personal crisis the night before, the nurse should consider the situation compassionately and flexibly, not applying the “consequences” rule or taking away the patient’s privileges. In turn, the nurse must weigh individual needs against the collective needs of all the patients. For a patient who is consistently late for treatment activities, the nurse should apply the rules of the unit even if it means taking away privileges.

Recently, concepts of milieu therapy have been applied to short-term inpatient and community settings. In acute care inpatient settings, nursing actions provide limits to and controls on patient behavior and provide structure and safety for the patients. Milieu treatments are based on the individual needs of the patients and include relaxation groups, discussion groups, and medication groups. Spontaneous and planned activities are possible on a short-term unit as well as in a long-term setting. In the community, it is possible to apply milieu therapy approaches in day treatment centers, group homes, and single dwellings.

Promotion of Patient Safety

Although the use of social rules of conduct and privilege systems can enhance smooth operation of a unit, some potentially serious problems can be associated with these practices. A most critical aspect of psychiatric–mental health nursing is the promotion of patient safety, especially in inpatient units.

Observation

Patient observation is the ongoing assessment of the patient’s mental status to identify and subvert any potential problem. An important process in all nursing practice, observation is particularly important in psychiatric nursing. In psychiatric settings, patients are ambulatory and thus more susceptible to environmental hazards. In addition, judgment and cognition impairment are symptoms of many psychiatric disorders. Often, patients are admitted because they pose a danger to themselves or others. In psychiatric nursing, observation is more than just “seeing” patients. It means continually monitoring them for any indication of harm to themselves or others.

All patients who are hospitalized for psychiatric reasons are continually

monitored. The intensity of the observation depends on their risk to themselves and others. Some patients are merely asked to “check in” at different times of the day, but others have a staff member assigned to only them, as in instances of potential suicide. Often “sharp,” such as razors, are locked up and given to patients at specified times. Mental health facilities and units all have policies that specify levels of observation for patients of varying degrees of risk.

De-escalation

De-escalation is an interactive process of calming and redirecting a patient who has an immediate potential for violence directed toward self or others. This intervention involves assessing the situation and preventing it from escalating to one in which injury occurs to the patient, staff, or other patients. After the nurse has assessed the situation, the nurse calmly calls to the patient and asks the individual to leave the situation. The nurse must avoid rushing toward the patient or giving orders (see Chapter 20). Nurses can use various interventions in this situation, including distraction, conflict resolution, and cognitive interventions.

Home Visits

Patients usually have been hospitalized or have received treatment for acute psychiatric symptoms before they are referred to psychiatric home service. The goal of **home visits**, the delivery of nursing care in the patient’s living environment, is to maximize the patient’s functional ability within the nurse–patient relationship and with the family or partner as appropriate. The psychiatric nurse who makes home visits needs to be able to work independently, is skilled in teaching patients and families, can administer and monitor medications, and uses community resources for the patient’s needs.

Home visits are especially useful in certain situations, including helping reluctant patients enter therapy, conducting a comprehensive assessment, strengthening a support network, and maintaining patients in the community when their condition deteriorates. Home visits are also useful in helping individuals comply with taking medication. The home visit process consists of three steps: the previsit phase, the home visit, and the postvisit phase. During previsit planning, the nurse sets goals for the home visit based on data received from other health care providers or the patient. In addition, the nurse and patient

agree on the time of the visit. As the nurse travels to the home, the nurse should assess the neighborhood for access to services, socioeconomic factors, and safety.

The actual visit can be divided into four parts. The first is the greeting phase, in which the nurse establishes rapport with family members. Greetings, which are usually brief, establish the communication process and the atmosphere for the visit. Greetings should be friendly but professional. In cultures that consider greetings important, this phase may involve more formal interactions, such as eating food or drinking tea with family members. The next phase establishes the focus of the visit. Sometimes, the purpose of the visit is medication administration, health teaching, or counseling. The patient and family must be clear regarding the purpose. The implementation of the service is the next phase and should use most of the visit time. If the purpose of the visit is problem-solving or decision-making, the family's cultural values may determine the types of interaction and decision-making approaches. Closure is the last phase, the end of the home visit. It is a time to summarize and clarify important points. The nurse should also schedule any additional visits and reiterate patient expectations between visits. Usually, the nurse is the only provider to see the patient regularly. The nurse should acknowledge family members on leaving if they were not a part of the visit.

The postvisit phase includes documentation, reporting, and follow-up planning. This is also when the nurse meets with the supervisor and presents data from the home visit at the team meeting.

Community Action

Nurses have a unique opportunity to promote mental health awareness and support humane treatment for people with mental disorders. Activities range from being an advisor to support groups to participating in the political process through lobbying efforts and serving on community mental health boards. These unpaid activities are usually outside the realm of a job. However, an important role of professionals is to provide community service in addition to service through income-generating positions.

EVALUATING OUTCOMES

Evaluation of patient outcomes involves answering the following questions:

- What is the cost effectiveness of the intervention?
- What benefits did the patient receive?
- What was the patient's level of satisfaction?
- Was the outcome specific or nonspecific to the patient's need?

Outcomes can be measured immediately after the nursing intervention or after time passes. For example, a patient may be able to resolve the acute depression and demonstrate confidence and improved self-esteem during a hospital stay. In various cases, it may be several months before the person can engage in positive interpersonal relationships.

SUMMARY OF KEY POINTS

- Assessment is the deliberate and systematic collection of information or data to determine current and past health, mental health, wellness, strengths, functional status, and present and past coping patterns.
- The assessment of the physical domain includes current and past health status; physical examination with review of body systems; review of physical functions; and pharmacologic, strength, and wellness assessment.
- The psychological assessment includes the mental status examination, behavioral responses, and risk factor assessment.
- The mental status examination includes general observation of appearance, psychomotor activity, and attitude; orientations; mood; affect; emotions; speech; and thought processes.
- Behavioral responses are assessed, as are self-concept and current and past coping patterns.
- Risk factor assessment includes ascertaining whether the patient has any suicidal, assaultive, or homicidal ideation.

- Psychological strengths and wellness attributes are summarized.
- The social assessment includes functional status; social systems; spirituality; occupational, economic, and legal status; quality of life; social strengths; and wellness attributes.
- The nursing assessment provides the data for nursing diagnoses and planning with the patient for mutually agreeable outcomes. Anticipated patient outcomes provide direction for psychiatric–mental health nursing interventions.
- Nursing interventions that are implemented for each domain include biologic (self-care, activity and exercise, sleep, nutrition, thermoregulation, and pain and medication management); psychological (counseling, conflict resolution, bibliotherapy, reminiscence, behavior therapy, psychoeducation, health teaching, and spiritual interventions); and social (behavior therapy and modification, milieu therapy, and various home and community interventions).
- Evaluation of patient outcomes involves assessing cost effectiveness of the interventions, benefits to the patient, and the patient’s level of satisfaction. Outcomes should be measurable, either immediately after intervention or after some time.

CRITICAL THINKING CHALLENGES

1. A 23-year-old White woman is admitted to an acute psychiatric setting for depression and suicidal gestures. This admission is her first, but she has experienced bouts of depression since early adolescence. She and her fiancé have just broken their engagement and moved into separate apartments. She has not yet told anyone that she is pregnant. She said that her mother had told her that she was “living in sin” and that she would “pay for it.” The patient wants to “end it all!” From this scenario, develop three important assessment questions related to her physical health and safety.
2. Identify normal laboratory values for sodium, blood urea nitrogen, liver enzymes, leukocyte count, and differential and thyroid functioning. Why are these values important to know?
3. Write a paragraph on your self-concept, including all three components: body

image, self-esteem, and personal identity. Explore the type of patient situations in which your self-concept can help your interactions with patients. Explore the types of patient situations in which your self-concept can hinder your interactions with patients.

- l. Tom, a 25-year-old man with schizophrenia, lives with his parents, who want to retire to Florida. Tom goes to work each day but relies on his mother for meals, laundry, and reminders to take his medication. Tom believes that he can manage the home, but his mother is concerned. She asks the nurse for advice about leaving her son to manage on his own. What approach would you use?
- i. Joan, a 35-year-old married woman, is admitted to an acute psychiatric unit for stabilization of her mood disorder. She is extremely depressed but refuses to consider a recommended medication change. She asks the nurse what to do. Using a nursing intervention, explain how you would approach Joan's problem.
- j. A nurse reports to work for the evening shift. The unit is chaotic. The television in the day room is loud; two patients are arguing about the program. Visitors are mingling in patients' rooms. The temperature of the unit is high. One patient is running up and down the hall yelling, "Help me, help me." Using a milieu therapy approach, what would you do to calm the unit?

Psychopharmacology, Dietary Supplements, and Biologic Interventions

Mary Ann Boyd

KEYCONCEPTS

- agonists
- antagonists
- pharmacokinetics
- pharmacodynamics

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Differentiate target symptoms from side effects.
2. Identify nursing interventions for common side effects of psychiatric medications.
3. Explain the role of the governmental regulatory process in the approval of medication and the use of other biologic interventions.
4. Discuss the pharmacodynamics of psychiatric medications.
5. Discuss the pharmacokinetics of psychiatric medications.
6. Explain the major classifications of psychiatric medications.
7. Identify typical nursing interventions related to the administration of psychiatric medications.
8. Analyze the potential benefits of other forms of somatic treatments, including herbal supplements, nutrition therapies, electroconvulsive therapy, light therapy, transcranial magnetic stimulation, and vagus nerve stimulation.
9. Evaluate the significance of nonadherence and discuss strategies supportive of medication adherence.

KEY TERMS

- Absorption
- Adherence
- Adverse reactions
- Affinity
- Akathisia
- Atypical antipsychotics
- Augmentation
- Bioavailability
- Biotransformation

INTRODUCTION

Recent scientific and technologic developments have opened the door for the development of new medications that treat mental disorders. Nurses administer these medications, monitor their effectiveness, and manage side effects; they also have an important role in educating patients about their medications. Psychiatric medications are increasingly prescribed in primary care settings, and nurses practicing in nonpsychiatric settings now need an in-depth knowledge of them.

This chapter focuses on the pharmacodynamics and pharmacokinetics of psychiatric medications. Included in this chapter is an overview of the major classes of psychopharmacologic drugs used in treating patients with mental disorders and the role of herbal supplements and nutritional therapies. In addition, other biologic treatments are discussed, including electroconvulsive therapy (ECT), light therapy, transcranial magnetic stimulation (rTMS), and vagus nerve stimulation (VNS).

PSYCHIATRIC MEDICATIONS

As with any drug, psychiatric medications are designated for use in certain conditions for specific symptoms. The nurse quickly realizes that these symptoms are present in several conditions, leading to many medications being prescribed for different diagnoses. Because medications can have both desirable and undesirable effects, it is important for the nurse to understand these factors to help ensure patient safety.

Target Symptoms and Side Effects

Psychiatric medications and other biologic interventions are indicated for **target**

symptoms, which are specific measurable symptoms expected to improve with treatment. Standards of care guide nurses in monitoring and documenting the effects of medications and other biologic treatments on target symptoms.

As yet, no drug has been developed that is so specific it affects only its target symptoms; instead, drugs typically act on several other organs and sites within the body. Even drugs with a high affinity and selectivity for a specific neurotransmitter will cause some responses in the body that are not related to the target symptoms. These unwanted effects of medications are called **side effects**. If unwanted effects have serious physiologic consequences, they are considered **adverse reactions**. The nurse monitors, documents, and reports the appearance of side effects and adverse reactions and implements nursing interventions for relief of medication side effects ([Table 12.1](#)).

BOX 12.1

Testing New Drugs for Safety and Efficacy

PHASES OF NEW DRUG TESTING

- Phase I: Testing defines the range of dosages tolerated in healthy individuals.
- Phase II: Effects of the drug are studied in a limited number of persons with the disorder. This phase defines the range of clinically effective dosage.
- Phase III: Extensive clinical trials are conducted at multiple sites throughout the country with larger numbers of patients. Efforts focus on corroborating the efficacy identified in phase II. Phase III concludes with a new drug application being submitted to the FDA.
- Phase IV: Drug studies continue after FDA approval to detect new or rare adverse reactions and potentially new indications. During this period, adverse reactions from the new medication should be reported to the FDA.

IMPLICATIONS FOR MENTAL HEALTH NURSES

- Throughout the phases, side effects and adverse reactions are monitored closely. The studies are tightly controlled, and strict regulations are enforced at each step.
- To prove drug effectiveness, diagnoses must be accurate, strict guidelines are followed, and subjects usually are not taking other medications and do not have complicating illnesses.
- A newly approved drug is approved only for the indications for which it has been tested.

Drug Regulation and Use

The U.S. Food and Drug Administration (FDA) is responsible for ensuring the safety, efficacy, and security of human and veterinary drugs, biologic products,

medical devices, nation's food supply, cosmetics, and products that emit radiation (www.FDA.gov). The FDA approves the labeling of medications and other biologic treatments after a thorough review of efficacy and safety data (Box 12.1). Nurses administering medications are responsible for knowing the labeling content, which is found in each medication's package insert or **Prescribing Information (PI)** and includes approved indications for the medication, side effects, adverse reactions, contraindications, and other important information. If the FDA identifies serious adverse reactions that can occur with the use of a specific medication, it may issue a warning found in a **boxed warning** in the PI. The nurse should be aware of these boxed warnings and monitor for the appearance of the adverse reactions. If a PI is not readily available, the labeling information is easily found on the FDA's website and in most pharmacy departments.

PSYCHOPHARMACOLOGY

A comparatively small amount of medication can have a significant and large impact on cell function and resulting behavior. When tiny molecules of medication are compared with the vast amount of cell surface in the human body, the fraction seems disproportionate. Yet, the drugs used to treat mental disorders often have profound effects on behavior. To understand how this occurs, one needs to understand both where and how drugs work. The following discussion highlights important concepts relevant to psychiatric medications.

TABLE 12.1 MANAGING COMMON SIDE EFFECTS OF PSYCHIATRIC MEDICATIONS

Side Effect or Discomfort	Intervention
Blurred vision	Reassurance (generally subsides in 2–6 wk).
Dry eyes	Artificial tears may be required; increased use of wetting solutions for those wearing contact lens. Alert ophthalmologist; no eye examination for new glasses for at least 3 wk after a stable dose.
Dry mouth and	Frequent rinsing of mouth, good oral hygiene, sucking sugarless

lips	candies or lozenges, lip balm, lemon juice, and glycerin mouth swabs.
Constipation	High-fiber diet; encourage bran, fresh fruits, and vegetables. Metamucil (must consume at least 16 oz of fluid with dose). Increase hydration. Exercise; increase fluids. Mild laxative.
Urinary hesitancy or retention	Monitor frequently for difficulty with urination, including changes in starting or stopping stream. Notify prescriber if difficulty develops. A cholinergic agonist, such as bethanechol, may be required.
Nasal congestion	Nose drops, moisturizer, <i>not</i> nasal spray
Sinus tachycardia	Assess for infections. Monitor pulse for rate and irregularities. Withhold medication and notify prescriber if resting rate exceeds 120 bpm.
Decreased libido, anorgasmia, ejaculatory inhibition	Reassurance (reversible); change to another medication.
Postural hypotension	Frequently monitor lying-to-standing blood pressure during dosage adjustment period, immediate changes and accommodation, and measure pulse in both positions; consider change to less antiadrenergic drug. Advise patient to get up slowly, sit for at least 1 min before standing (dangling legs over side of bed), and stand for 1 min before walking or until lightheadedness subsides. Increase hydration, avoid caffeine. Elastic stockings if necessary. Notify prescriber if symptoms persist or significant blood pressure changes are present; medication may have to be changed if patient does not have impulse control to get up slowly.
Photosensitivity	Protective clothing. Dark glasses.
Dermatitis	Use of sun block; remember to cover all exposed areas. Stop medication usage.

	Consider medication change; may require a systemic antihistamine. Initiate comfort measures to decrease itching.
Impaired psychomotor functions	Advise patient to avoid dangerous tasks, such as driving. Avoid alcohol, which increases this impairment.
Drowsiness or sedation	Encourage activity during the day to increase accommodation. Avoid tasks that require mental alertness, such as driving. May need to adjust dosing schedule or, if possible, give a single daily dose at bedtime. May need a cholinergic medication if sedation is the problem. Avoid driving or operating potentially dangerous equipment. May need change to less sedating medication. Provide quiet and decreased stimulation when sedation is the desired effect.
Weight gain and metabolic changes	Exercise and diet teaching. Caloric control.
Edema	Check fluid retention. Reassurance. May need a diuretic.
Irregular menstruation or amenorrhea	Reassurance (reversible). May need to change class of drug. Reassurance and counseling (does not indicate lack of ovulation). Instruct patient to continue birth control measures.
Vaginal dryness	Instruct in use of lubricants.

Pharmacodynamics: Where Drugs Act

Drug molecules act at specific sites, not on the entire cell surface. Psychiatric medications primarily target the central nervous system (CNS) at the cellular, synaptic level at four sites: receptors, ion channels, enzymes, and carrier proteins.

KEYCONCEPT Pharmacodynamics is the action or effect of drugs on living organisms.

Receptors

Receptors are specific proteins intended to respond to a chemical (i.e., neurotransmitter) normally present in blood or tissues (see [Chapter 8](#)). Receptors also respond to drugs with similar chemical structures. When drugs attach to a receptor, they can act as **agonists**—substances that initiate the same response as the chemical normally present in the body—or as **antagonists**—substances that block the response of a given receptor. [Figure 12.1](#) illustrates the action of an agonist and an antagonist drug at a receptor site. A drug's ability to interact with a given receptor type may be judged by three properties: selectivity, affinity, and **intrinsic activity**.

FIGURE 12.1 Agonist and antagonist drug actions at a receptor site. This schematic drawing represents drug–receptor interactions. At the *top*, drug D has the correct shape to fit receptor R, forming a drug–receptor complex, which results in a conformational change in the receptor and the opening of a pore in the adjacent membrane. Drug D is an agonist. At the *bottom*, drug A also has the correct shape to fit the receptor, forming a drug–receptor complex, but in this case, there is no conformational change and therefore no response. Drug A is, therefore, an antagonist.

KEYCONCEPT Agonists (mimic the neurotransmitter) have all three properties: selectivity, affinity, and intrinsic activity. **Antagonists** (block the receptor) have only selectivity and affinity properties; they do not have intrinsic activity because they produce no biologic response by attaching to the receptor.

Some drugs are referred to as **partial agonists** because they have some intrinsic activity (although weak). Because there are no “pure” drugs affecting only one neurotransmitter, most drugs have multiple effects. A drug may act as an agonist for one neurotransmitter and an antagonist for another. Medications that have both agonist and antagonist effects are called mixed agonist–antagonists.

Selectivity

Selectivity is the ability of a drug to be specific for a receptor. If a drug is highly selective, it will interact only with its specific receptors in the areas of the body where these receptors occur and therefore not affect tissues and organs where its receptors do not occur. Using a “lock-and-key” analogy, only a specific, highly selective key will fit a given lock. The more selective or structurally specific a drug is, the more likely it will affect only the specific receptor for which it is meant. The less selective the drug, the more receptors are affected and the more likely there will be unintended effects or side effects.

Affinity

Affinity is the degree of attraction or strength of the bond between the drug and its biologic target. Affinity is strengthened when a drug has more than one type of chemical bond with its target. If a cell membrane contains several receptors to which a drug will adhere, the affinity is increased. The weaker the chemical bond, the more likely a drug’s effects are reversible. Most drugs used in psychiatry adhere to receptors through weak chemical bonds, but some drugs, specifically the monoamine oxidase inhibitors (MAOIs; discussed later), have a different type of bond, called a covalent bond. A covalent bond is formed when two atoms share a pair of electrons. This type of bond is stronger and irreversible at normal temperatures. The effects of the drugs that form covalent bonds are often called “irreversible” because they are long lasting, taking several weeks to resolve. Knowledge of a medication’s affinity for receptors and subtypes of receptors may give some indication of the likelihood that specific target symptoms might improve and what side effects might be predicted.

Intrinsic Activity

A drug's ability to interact with a given receptor is its intrinsic activity, or the ability to produce a response after it becomes attached to the receptor. Some drugs have selectivity and affinity but produce no response. An important measure of a drug is whether it produces a change in the cell containing the receptor.

Ion Channels

Some drugs directly block the ion channels of the nerve cell membrane. For example, the antianxiety benzodiazepine drugs, such as diazepam (Valium), bind to a region of the gamma aminobutyric acid (GABA) receptor–chloride channel complex, which helps to open the chloride ion channel. In turn, the activity of GABA is enhanced.

Enzymes

Enzymes are usually proteins that act as catalysts for physiologic reactions and can be targets for drugs. For example, monoamine oxidase (MAO) is an enzyme required to break down neurotransmitters associated with depression (norepinephrine, serotonin, and dopamine). The MAOI antidepressants inhibit this enzyme, resulting in more neurotransmitter activity.

Carrier Proteins: Uptake Receptors

A **carrier protein** is a membrane protein that transports a specific molecule across the cell membrane. Carrier proteins (also referred to as **uptake receptors**) recognize sites specific for the type of molecule to be transported. When a neurotransmitter is removed from the synapse, specific carrier molecules return it to the presynaptic nerve, where most of it is stored to be used again. Medications specific for this site block or inhibit this transport and therefore increase the activity of the neurotransmitter in the synapse. [Figure 12.2](#)

illustrates the reuptake blockade.

Clinical Concepts

Efficacy is the ability of a drug to produce a response and is considered when a drug is selected. The degree of receptor occupancy contributes to the drug's efficacy, but a drug may occupy many receptors and not produce a response. [Table 12.2](#) provides a brief summation of possible physiologic effects from drug actions on specific neurotransmitters. This information should serve only as a guide in predicting side effects because many physical outcomes or behaviors resulting from neural transmission are controlled by multiple receptors and neurotransmitters.

Potency refers to the dose of drug required to produce a specific effect. One drug may be able to achieve the same clinical effect as another drug but at a lower dose, making it more potent. Although the drug given at the lower dose is more potent because both drugs achieve similar effects, they may be considered to have equal efficacy.

FIGURE 12.2 Reuptake blockade of a carrier molecule for serotonin by a selective serotonin reuptake inhibitor.

Note. SSRI = selective serotonin reuptake inhibitor.

TABLE 12.2 DRUG ACTIONS ON NEUROTRANSMITTERS

Action by Drug on

Neurotransmitter Physiologic Effects

Example of Drugs

Reuptake Inhibition

Norepinephrine reuptake inhibition

Antidepressant action
Potentiation of pressor effects of norepinephrine
Interaction with guanethidine
Side effects: tachycardia, tremors, insomnia,

Desipramine
Venlafaxine

Serotonin reuptake inhibition	erectile, and ejaculation dysfunction	
	Antidepressant action	Fluoxetine
	Antiobsessional effect	Fluvoxamine
	Increase or decrease in anxiety (dose dependent)	
	Side effects: gastrointestinal distress; nausea; headache; nervousness; motor restlessness; and sexual side effects, including anorgasmia	
Dopamine reuptake inhibition	Antidepressant action	Bupropion
	Antiparkinsonian effect	
	Side effects: increase in psychomotor activity, aggravation of psychosis	

Receptor Blockade

Histamine receptor blockade (H ₁)	Side effects: sedation, drowsiness, hypotension, and weight gain	Quetiapine
		Imipramine
		Clozapine
		Olanzapine
Acetylcholine receptor blockade (muscarinic)	Side effects: anticholinergic (dry mouth, blurred vision, constipation, urinary hesitancy and retention, memory dysfunction) and sinus tachycardia	Imipramine
		Amitriptyline
		Olanzapine
Norepinephrine receptor blockade (α_1 receptor)	Potential of antihypertensive effect of prazosin and terazosin	Amitriptyline Clomipramine
	Side effects: postural hypotension, dizziness, reflex tachycardia, sedation	Clozapine
Norepinephrine receptor blockade (α_2 receptor)	Increased sexual desire (yohimbine)	Amitriptyline Clomipramine
	Interactions with antihypertensive medications, blockade of the antihypertensive effects of clonidine	Clozapine Trazodone Yohimbine
Norepinephrine receptor blockade (β_1 receptor)	Side effect: priapism	
	Antihypertensive action (propranolol) Side effects: orthostatic hypotension, sedation, depression, sexual dysfunction (including impotence and decreased ejaculation)	Propranolol
Serotonin receptor	Antidepressant action	Trazodone

blockade (5-HT _{1a})	Antianxiety effect Possible control of aggression	Risperidone Ziprasidone
Serotonin receptor blockade (5-HT ₂)	Antipsychotic action Some antimigraine effect Decreased rhinitis Side effects: hypotension, ejaculatory problems	Risperidone Clozapine Olanzapine Ziprasidone
Dopamine receptor blockade (D ₂)	Antipsychotic action Side effects: extrapyramidal symptoms, such as tremor, rigidity (especially acute dystonia and parkinsonism); endocrine changes, including elevated prolactin levels	Haloperidol Ziprasidone

In some instances, the effects of medications diminish with time, especially when they are given repeatedly, as in the treatment of chronic psychiatric disorders. This loss of effect is most often a form of physiologic adaptation that may develop as the cell attempts to regain homeostatic control to counteract the effects of the drug. There are many reasons for decreased drug effectiveness ([Box 12.2](#)).

Desensitization is a rapid decrease in drug effects that may develop in a few minutes of exposure to a drug. This reaction is rare with most psychiatric medications but can occur with some medications used to treat serious side effects (e.g., physostigmine, sometimes used to relieve severe anticholinergic side effects). A rapid decrease can also occur with some drugs because of immediate transformation of the receptor when the drug molecule binds to the receptor. Other drugs cause a decrease in the number of receptors or exhaust the mediators of neurotransmission.

BOX 12.2

Mechanisms Causing Decreases in Medication Effects

- Change in receptors
- Loss of receptors
- Exhaustion of neurotransmitter supply
- Increased metabolism of the drug
- Physiologic adaptation

Tolerance is a gradual decrease in the action of a drug at a given dose or

concentration in the blood. This decrease may take days or weeks to develop and results in loss of therapeutic effect of a drug. For therapeutic drugs, this loss of effect is often called *treatment refractoriness*. In the abuse of substances such as alcohol or cocaine, tolerance is a part of the addiction (see Chapter 31).

Toxicity generally refers to the point at which concentrations of the drug in the bloodstream are high enough to become harmful or poisonous to the body. Individuals vary widely in their responses to medications. Some patients experience adverse reactions more easily than others. The **therapeutic index** is the ratio of the maximum nontoxic dose to the minimum effective dose. A high therapeutic index means that there is a large range between the dose at which the drug begins to take effect and a dose that would be toxic to the body. Drugs with a low therapeutic index have a narrow range.

This concept of toxicity has some limitations. The range can be affected by drug tolerance. For example, when tolerance develops, the person increases the dosage, which makes them more susceptible to an accidental suicide. The therapeutic index of a medication also may be greatly changed by the coadministration of other medications or drugs. For example, alcohol consumed with most CNS-depressant drugs will have added depressant effects, greatly increasing the likelihood of toxicity or death.

Pharmacokinetics: How the Body Acts on the Drugs

The field of pharmacokinetics studies the process of how drugs are acted on by the body through absorption, distribution, metabolism (biotransformation), and excretion. Pharmacokinetics for specific medications is always explained in a drug's PI. Together with the principles of pharmacodynamics, this information is helpful in monitoring drug effects and predicting behavioral response.

KEYCONCEPT Pharmacokinetics is the process by which a drug is absorbed, distributed, metabolized, and eliminated by the body.

Absorption and Routes of Administration

The first phase of **absorption** is the movement of the drug from the site of administration into the plasma. The typical routes of administration of

psychiatric medications include oral (tablet, capsule, and liquid), deltoid and gluteal intramuscular (IM; short- and long-acting agents), and intravenous (IV; rarely used for treatment of the primary psychiatric disorder but instead for rapid treatment of adverse reactions). A transdermal patch antidepressant and oral inhalation are also available. The advantages and disadvantages of each route and the subsequent effects on absorption are listed in [Table 12.3](#).

Drugs taken orally are usually the most convenient for the patient; however, this route is also the most variable because absorption can be slowed or enhanced by several factors. Taking certain drugs orally with food or antacids may slow the rate of absorption or change the amount of the drug absorbed. For example, antacids containing aluminum salts decrease the absorption of most antipsychotic drugs; thus, antacids must be given at least 1 hour before administration or 2 hours after.

Oral preparations are absorbed from the gastrointestinal tract into the bloodstream through the portal vein and then to the liver. They may be metabolized within the gastrointestinal wall or liver before reaching the rest of the body. This is called the **first-pass effect**. The consequence of first-pass effect is that only a fraction of the drug reaches systemic circulation. Oral dosages are adjusted for the first-pass effect. That is, the dose of the oral form is significantly higher than the IM or IV formulations.

Bioavailability describes the amount of the drug that reaches systemic circulation unchanged. The route by which a drug is administered significantly affects bioavailability. With some oral drugs, the amount of drug entering the bloodstream is decreased by first-pass metabolism, and bioavailability is lower. On the other hand, some rapidly dissolving oral medications have increased bioavailability.

Concept Mastery Alert

First-pass effect refers to the metabolism that a drug undergoes within the gastrointestinal wall or liver before reaching the rest of the body.

Bioavailability describes the amount of a drug that reaches the systemic circulation unchanged.

TABLE 12.3 SELECTED FORMS AND ROUTES OF PSYCHIATRIC MEDICATIONS

**Preparation and
Route**

Examples

Advantages

Disadvantages

Oral tablet	Basic preparation for most psychopharmacologic agents, including antidepressants, antipsychotics, mood stabilizers, anxiolytics, and so on	Usually most convenient	Variable rate and extent of absorption, depending on the drug May be affected by the contents of the intestines May show first-pass metabolism effects May not be easily swallowed by some individuals
Oral liquid	Also known as concentrates The antipsychotic risperidone The antidepressant fluoxetine Antihistamines, such as diphenhydramine Mood stabilizers, such as lithium citrate	Ease of incremental dosing Easily swallowed In some cases, more quickly absorbed	More difficult to measure accurately Depending on drug: <ul style="list-style-type: none">• Possible interactions with other liquids such as juice, forming precipitants• Possible irritation to mucosal lining of mouth if not properly diluted
Rapidly dissolving tablet	Atypical antipsychotics, such as olanzapine, risperidone, asenapine	Dissolves almost instantaneously in mouth	Patient needs to remember to have completely dry hands and to

			place tablet in mouth immediately. Tablet should not linger in the hand. Handy for people who have trouble swallowing or for patients who let medication linger in the cheek for later expectoration Can be taken when water or other liquid is unavailable
Intramuscular	Some antipsychotics, such as ziprasidone, olanzapine, haloperidol, and chlorpromazine Anxiolytics, such as lorazepam Anticholinergics, such as benztropine mesylate No antidepressants No mood stabilizers	More rapid acting than oral preparations No first-pass metabolism	Injection-site pain and irritation Some medications may have erratic absorption if heavy muscle tissue at the site of injection is not in use.
Intramuscular depot (or long acting)	Risperidone (Risperdal Consta), paliperidone palmitate (Invega Sustenna), olanzapine (Zyprexa Relprevv), aripiprazole (Abilify Maintena),	May be more convenient for some individuals who have difficulty	Pain at injection site

	aripiprazole lauroxil (Aristada), haloperidol decanoate, fluphenazine decanoate	following medication regimens	
Intravenous	Anticholinergics, such as diphenhydramine, benztropine mesylate Anxiolytics, such as diazepam, lorazepam, and chlordiazepoxide	Rapid and complete availability to systemic circulation	Inflammation of tissue surrounding site Often inconvenient for patient and uncomfortable Continuous dosage requires use of a constant rate IV infusion
Subcutaneous (abdominal)	Risperidone (Perseris)	More convenient than oral regime; injection in abdomen may be preferable to the gluteus.	Pain at injection site
Transdermal patch	Antidepressant, selegiline	Avoid daily oral ingestion of medication.	Skin irritation
Oral inhalation	Conventional antipsychotic, loxapine	Rapidly absorbed to treat psychomotor agitation	Bronchospasm
Intranasal spray	Antidepressant, esketamine	Rapidly absorbed to treat severe depression	Nasal discomfort Oropharyngeal pain Throat irritation

Note. IV = intravenous.

Distribution

Distribution of a drug is the amount of the drug found in various tissues, particularly the target organ at the site of drug action. Factors that affect distribution include the size of the organ; amount of blood flow or perfusion within the organ; solubility of the drug; plasma protein binding (the degree to which the drug binds to plasma proteins); and anatomic barriers, such as the blood–brain barrier, that the drug must cross. A psychiatric drug may have rapid absorption and high bioavailability, but if it does not cross the blood–brain barrier to reach the CNS, it is of little use. [Table 12.4](#) provides a summary of how some significant factors affect distribution. Two of these factors, solubility (ability of a drug to dissolve) and protein binding, warrant additional discussion about how they relate to psychiatric medications.

Solubility

Substances may cross a membrane in several ways, but passive diffusion is by far the simplest. To do this, the drug must dissolve in the structure of the cell membrane. Therefore, the **solubility** of a drug is an important characteristic. Being soluble in lipids allows a drug to cross most of the membranes in the body, and the tissues of the CNS are less permeable to water-soluble drugs than are other areas of the body. Most psychopharmacologic agents are lipid soluble and easily cross the blood–brain barrier. However, this characteristic means that psychopharmacologic agents also cross the placenta; consequently, most are contraindicated during pregnancy.

TABLE 12.4 FACTORS AFFECTING DISTRIBUTION OF A DRUG

Factor	Effect on Drug Distribution
---------------	------------------------------------

Size of the organ	Larger organs require more drug to reach a concentration level equivalent to other organs and tissues.
Blood	The more blood flow to and within an organ (perfusion), the greater

flow to the drug concentration. The brain has high perfusion.
the organ

Solubility The greater the solubility of a drug within a tissue, the greater its
of the concentration.
drug

Plasma If a drug binds well to plasma proteins, particularly to albumin, it will
protein stay in the body longer but have a slower distribution.
binding

Anatomic Both the gastrointestinal tract and the brain are surrounded by layers of
barriers cells that control the passage or uptake of substances. Lipid-soluble
substances are usually readily absorbed and pass the blood–brain
barrier.

Protein Binding

Of considerable importance is the degree to which a drug binds to plasma proteins. Only unbound or “free” drugs act at the receptor sites. High **protein binding** reduces the concentration of the drug at the receptor sites. However, because the binding is reversible, as the unbound drug is metabolized, more drug is released from the protein bonds. Drugs are also released from storage in the fat depots. These processes can prolong the duration of action of the drug. When patients stop taking their medication, they often do not experience an immediate return of symptoms because they continue to receive the drug as it is released from storage sites in the body.

Metabolism

Metabolism, also called **biotransformation**, is the process by which a drug is altered and broken down into smaller substances, known as metabolites. Most metabolism occurs in the liver, but it can also occur in the kidneys, lungs, and intestines. Phase I includes oxidation, hydrolysis, and reduction reactions. In most cases, **metabolites** are inactive but in some psychiatric drugs, such as norfluoxetine (metabolite of fluoxetine [Prozac]), they are also active. Phase II reactions or conjugation combines a drug or metabolite with other chemicals. Through the phases of biotransformation, lipid-soluble drugs eventually become more water soluble so they may be readily excreted.

Phase I oxidation reactions are carried out by the **cytochrome P450 (CYP450) system**, a set of microsomal enzymes (usually hepatic) referred to as CYP1, CYP2, and CYP3. Within each CYP family, there are enzyme subgroups identified by a number–letter sequence (i.e., 1A2 or 3A4). There are more than 50 enzymes, but most of the metabolism occurs in only a few of them. A **substrate** is the drug or compound that is identified as a target of an enzyme. For example, clozapine is the substrate for the CYP1A2 enzyme.

The functioning of these enzymes is influenced by drugs and other chemical substances. An **inhibitor** of a CYP enzyme slows down metabolism, which in turn decreases the clearance of the substrate and elevates its plasma level. An **inducer** speeds up metabolism, which in turn increases the clearance of the substrate and decreases its plasma level. For example, cigarette smoke is a potent inducer of CYP1A2, which in turn speeds up the clearance of clozapine and decreases its plasma level. A smoker will clear clozapine faster than a nonsmoker even though both take the same dose.

A **drug–drug interaction** can occur if one substance inhibits an enzyme system. For example, nortriptyline (an antidepressant with a narrow therapeutic index) is the substrate of the CYP2D6 enzyme. By adding paroxetine (a selective serotonin reuptake inhibitor [SSRI] antidepressant and an inhibitor of the CYP2D6 enzyme), the 2D6 enzyme is inhibited, and the level of nortriptyline in the blood increases. Toxicity can easily develop because of a low therapeutic index. The PI informs the nurse which drugs should not be given together.

Each human CYP450 enzyme is an expression of a unique gene. The science of pharmacogenomics blends pharmacology with genetic knowledge and is concerned with understanding and determining an individual's specific CYP450 makeup and then individualizing medications to match the person's CYP450 profile. Genetically (inherited as an autosomal recessive trait), some individuals are poor metabolizers, and others may be rapid metabolizers. Whereas poor metabolizers are more likely to have adverse reactions, rapid metabolizers may not allow certain drugs to reach therapeutic levels. Research has suggested that there are variations among ethnic groups with poor metabolizers accounting for up to 7% of White individuals for CYP2D6 and up to 25% of East Asians for CYP2C19. Knowing whether patients are poor or rapid metabolizers is important because most psychiatric medications are metabolized by these enzymes. DNA laboratory tests are available for patients who have a personal or family history of adverse drug reactions to medications metabolized by 2D6 and 2D19 to confirm the presence of genotypes that affect metabolism. Enzyme

CYP2D6 is important in the metabolism of many antidepressants and antipsychotics, and CYP2C19 is important for some antidepressant metabolism (Walden et al., 2019).

Excretion

Excretion refers to the removal of drugs from the body either unchanged or as metabolites. **Clearance** refers to the total volume of blood, serum, or plasma from which a drug is completely removed per unit of time to account for the excretion. The half-life of a drug provides a measure of the expected rate of clearance. **Half-life** refers to the time required for plasma concentrations of the drug to be reduced by 50%. For most drugs, the rate of excretion slows, but the half-life remains unchanged. It usually takes four half-lives or more of a drug in total time for more than 90% of a drug to be eliminated.

Drugs bound to plasma proteins do not cross the glomerular filter freely. These lipid-soluble drugs are passively reabsorbed by diffusion across the renal tubule and thus are not rapidly excreted in the urine. Because many psychiatric medications are protein bound and lipid soluble, most of their excretion occurs through the liver, where they are excreted in the bile and delivered into the intestine. Lithium and gabapentin, mood stabilizers, are notable examples of renal excretion. Any impairment in renal function or renal disease may lead to toxic symptoms.

Dosing refers to the administration of medication over time so that therapeutic levels may be achieved or maintained without reaching toxic levels. In general, it is necessary to give a drug at intervals no greater than the half-life of the medication to avoid excessive fluctuation of concentration in the plasma between doses. With repeated dosing, a certain amount of the drug is accumulated in the body.

Steady-state plasma concentration, or simply **steady state**, occurs when absorption equals excretion and the therapeutic level plateaus. The rate of accumulation is determined by the half-life of the drug. Drugs generally reach steady state in four to five times the elimination half-life. However, because elimination or excretion rates may vary significantly in any individual, fluctuations may still occur, and dose schedules may need to be modified.

Individual Variations in Drug Effects

Many factors affect drug absorption, distribution, metabolism, and excretion. These factors may vary among individuals, depending on their age, genetics, and ethnicity.

Age

Pharmacokinetics is significantly altered at the extremes of the life cycle. Gastric absorption changes as individuals' age. Gastric pH increases, and gastric emptying decreases. Gastric motility slows and splanchnic circulation is reduced. Normally, these changes do not significantly impair oral absorption of a medication, but addition of common conditions, such as diarrhea, may significantly alter and reduce absorption. Malnutrition, cancer, and liver disease decrease the production of the primary protein albumin. More free drug is acting in the system, producing higher blood levels of the medication and potentially toxic effects. The activity of hepatic enzymes also slows with age. As a result, the ability of the liver to metabolize medications may slow as much as a fourfold decrease between the ages of 20 and 70 years. Production of albumin by the liver generally declines with age. Changes in the parasympathetic nervous system produce a greater sensitivity in older adults to anticholinergic side effects, which are more severe with this age group.

Renal function also declines with age. Creatinine clearance in a young adult is normally 100 to 120 mL/min, but after age 40, this rate declines by about 10% per decade (Delanaye et al., 2019). Medical illnesses, such as diabetes and hypertension, may contribute to further decline of renal function. When creatinine clearance falls below 30 mL/min, the excretion of drugs by the kidneys is significantly impaired, and potentially toxic levels may accumulate.

Pharmacogenetics and Ethnopsychopharmacology

Pharmacogenomics is the study of how a person's genetic makeup affects their response to drugs. There are important genetic variations that influence the metabolism and action of psychotropic drugs in different ethnic groups. Various tests are used to predict genetic responses to drugs and the potential for adverse effects. For example, studies show that selecting antidepressants according to genetic profile can improve treatment outcomes for people with depression and

anxiety (Bradley et al., 2018).

Overlapping pharmacogenetics is the field of **ethnopsychopharmacology**, the study of how culture and genetic differences in human groups determine and influence the response to medications. Ethnopsychopharmacology focuses on the impact of cultural practices, such as consuming foods or ingesting beverages, on genetic variations in metabolism, on complementary and alternate health care practices, and on herbal substances.

Although ethnic and racial groups are genetically heterogeneous, there are population differences in disease susceptibility (Roberts & Erdei, 2020). For example, some individuals of Asian descent produce higher concentrations of acetaldehyde with alcohol use than do those of European descent, resulting in a higher incidence of adverse reactions such as flushing and palpitations. Asians often require one half to one third the dose of antipsychotic medications and lower doses of antidepressants than Whites require (Matsushita & Higuchi, 2017). In the African populations, there is a high degree of variability in the dosage of many medications (Nievergelt et al., 2019).

PHASES OF DRUG TREATMENT AND THE NURSE'S ROLE

Phases of drug treatment include initiation, stabilization, maintenance, and discontinuation of the medication. The following explains the role of the nurse in these phases.

Initiation Phase

Before the initiation of medications, patients must undergo several assessments.

- A psychiatric evaluation to determine the diagnosis and target symptoms
- A nursing assessment that includes cultural beliefs and practices (see Chapter 12)
- Physical examination and indicated laboratory tests, often including baseline determinations such as a complete blood count (CBC), liver and kidney function tests, electrolyte levels, urinalysis, and possibly thyroid function tests and electrocardiography (ECG), to determine whether a physical

condition may be causing the symptoms and to establish that it is safe to initiate use of a particular medication

During the initiation of medication, the nurse assesses, observes, and monitors the patient's response to the medication; teaches the patient about the action, dosage, frequency of administration, and side effects; and develops a plan for ongoing contact with clinicians. The first medication dose should be treated as if it were a "test" dose. Patients should be monitored for adverse reactions such as changes in blood pressure, pulse, or temperature; changes in mental status; allergic reactions; dizziness; ataxia; or gastric distress. If any of these symptoms develop, they should be reported to the prescriber.

Stabilization Phase

During stabilization, the prescriber adjusts or titrates the medication dosage to achieve the maximum amount of improvement with a minimum of side effects. Psychiatric-mental health nurses assess for improvements in the target symptoms and for the appearance of side effects. If medications are being increased rapidly, such as in a hospital setting, nurses must closely monitor temperature, blood pressure, pulse, mental status, common side effects, and unusual adverse reactions.

In the outpatient setting, nurses focus on patient education, emphasizing the importance of taking the medication, expected outcomes, and potential side effects. Patients need to know how and when to take their medications, how to minimize any side effects, and which side effects require immediate attention. A plan should be developed for patients and their families to clearly identify what to do if adverse reactions develop. The plan, which should include emergency telephone numbers or available emergency treatment, should be reviewed frequently.

Therapeutic drug monitoring is most important in this phase of treatment. Many medications used in psychiatry improve target symptoms only when a therapeutic level of medication has been obtained in the individual's blood. Some medications, such as lithium, have a narrow therapeutic range and must be monitored frequently and accurately. Nurses must be aware of when and how these levels are to be determined and assist patients in learning these procedures. Because of protein binding and lipid solubility, most medications do not have

obtainable plasma levels that are clinically relevant. However, plasma levels of these medications may still be requested to evaluate further such issues as absorption and adverse reactions.

Sometimes, the first medication chosen does not adequately improve the patient's target symptoms. In such cases, use of the medication will be discontinued, and treatment with a new medication will be started. Medications may also be changed when adverse reactions or seriously uncomfortable side effects occur, or these effects substantially interfere with the individual's quality of life. Nurses should be familiar with the pharmacokinetics of both drugs to be able to monitor side effects and possible drug–drug interactions during this change.

At times, an individual may show only partial improvement from a medication, and the prescriber may try an **augmentation** strategy by adding another medication. For example, a prescriber may add a mood stabilizer, such as lithium, to an antidepressant to improve the effects of the antidepressant. **Polypharmacy**, using more than one group from a class of medications, is increasingly being used as an acceptable strategy with most psychopharmacologic agents to match the drug action to the neurochemical needs of the patient. Nurses must be familiar with the potential effects, side effects, drug interactions, and rationale for the treatment regimen.

Maintenance Phase

After the individual's target symptoms have improved, medications are usually continued to prevent **relapse** or return of the symptoms. In some cases, this may occur despite the patient's continued use of the medication. Patients must be educated about their target symptoms and have a plan of action if the symptoms return. In other cases, the patient may experience medication side effects. The psychiatric–mental health nurse has a central role in assisting individuals to monitor their own symptoms, identify emerging side effects, manage psychosocial stressors, and avoid other factors that may cause the medications to lose effect.

Discontinuation Phase

Some psychiatric medications will be discontinued; others will not. Some require a tapered discontinuation, which involves slowly reducing dosage while monitoring closely for reemergence of the symptoms. Some psychiatric disorders, such as mild depression, respond to treatment and do not recur. Other disorders, such as schizophrenia, usually require lifetime medication. Discontinuance of some medications, such as controlled substances, produces withdrawal symptoms; discontinuance of others does not.

MAJOR PSYCHOPHARMACOLOGIC DRUG CLASSES

Major classes of psychiatric drugs include antipsychotics, mood stabilizers, antidepressants, antianxiety and sedative–hypnotic medications, and stimulants.

Antipsychotic Medications

Antipsychotic medications can be thought of as “newer” and “older” medications. Newer or **atypical antipsychotics** appear to be equally or more effective but have fewer side effects than the traditional older agents. The term *typical* or **conventional antipsychotics** identifies the older antipsychotic drugs. [Table 12.5](#) provides a list of selected antipsychotics.

Indications and Mechanism of Action

Antipsychotic medications are indicated for schizophrenia, mania, and autism and to treat the symptoms of psychosis, such as hallucinations, delusions, bizarre behavior, disorganized thinking, and agitation. (These symptoms are described more fully in later chapters.) These medications also reduce aggressiveness, and inappropriate behavior associated with psychosis. Within the typical antipsychotics, haloperidol and pimozide are approved for treating patients with Tourette syndrome, reducing the frequency and severity of vocal tics. Some of the typical antipsychotics, particularly chlorpromazine, are used as antiemetics or for postoperative intractable hiccoughs.

The atypical antipsychotic medications differ from the typical antipsychotics in that they block serotonin receptors more potently than the dopamine receptors. The difference between the mechanism of action of the typical and atypical antipsychotics helps to explain their differences in terms of effect on target symptoms and in the degree of side effects they produce.

Pharmacokinetics

Antipsychotic medications administered orally have a variable rate of absorption complicated by the presence of food, antacids, smoking, and even the coadministration of anticholinergics, which slow gastric motility. Clinical effects begin to appear in about 30 to 60 minutes. Absorption after IM administration is less variable because this method avoids the first-pass effects. Therefore, IM administration produces greater bioavailability. It is important to remember that IM medications are absorbed more slowly when muscles are not used. Typically, the deltoid is used more than the gluteal muscles, which may account for faster absorption of medication and which has better blood perfusion.

Metabolism of these drugs occurs almost entirely in the liver with the exception of paliperidone (Invega, Sustenna), which is not extensively metabolized by the liver but is excreted largely unchanged through the kidney, and Lurasidone (Latuda), which is excreted through the urine and feces. Most antipsychotics are subject to the effects of other drugs that induce or inhibit the liver enzymes described earlier (see [Table 12.6](#)). Careful observance of concurrent medication use, including prescribed, over the counter, and substances of abuse, is required to avoid drug–drug interactions. For example, atypical antipsychotic concentrations may be affected by CYP450-inhibiting drugs such as paroxetine and fluoxetine.

TABLE 12.5 ANTIPSYCHOTIC MEDICATIONS

Generic (Trade) Drug Name	Usual Dosage Range	Half-Life	Route of Administration
Atypical Antipsychotics			

Aripiprazole (Abilify)	10–30 mg/day	75–94 h	Oral tablets, injection, disintegrating tablet
Aripiprazole (Abilify MyCite)	10–30 mg/day	75–49 h	Oral tablet embedded with an ingestible event marker sensor intended to track drug ingestion
Aripiprazole (Maintena)	200–400 mg	29.9–46.6 days	Injection
Aripiprazole lauroxil (Aristada)	441–882 mg monthly	29.2–34.9 days	Injection
Asenapine (Saphris)	5–10 mg BID	24 h	Sublingual tablet
Brexpiprazole (Rexulti)	0.5–1.0 mg/day	86–91 h	Oral tablet
Cariprazine (Vraylar)	1.5–6.0 mg/day	2–4 days 1–3 wk (metabolite)	Oral capsule
Clozapine (Clozaril, Fazaclo, Versacloz)	300–900 mg/day	4–12 h	Oral tablet, disintegrating tablet, oral suspension
Iloperidone (Fanapt)	6–12 mg BID	18–33 h	Oral tablet
Lurasidone (Latuda)	40 mg/day	18 h	Oral tablet
Olanzapine (Zyprexa)	5–15 mg/day 2.5–10 mg/day IM	21–54 h	Oral tablet, disintegrating tablet Injection
Olanzapine (Relprevv)	150–300 mg q2–4wk	30 days	Injection
Paliperidone (Invega Extended Release)	3–12 mg once daily in <i>am</i>	23 h	Oral
Paliperidone (Invega Sustenna)	117 mg monthly	29–49 days	Injection
Pimavanserin (Nuplazid)	34 mg once daily	5 h for 17 mg	Oral tablet

Quetiapine fumarate (Seroquel)	150–750 mg/day	7 h	Oral tablet
Risperidone (Risperdal)	2–8 mg/day	20 h	Oral tablet, oral solution, disintegrating tablet
Risperdal (Consta)	25–50 mg q2wk	3–6 days	IM Injection
Risperidone (Perseris)	90 or 120 mg once monthly	9–11 days	Abdominal subcutaneous injection
Ziprasidone HCl (Geodon)	40–160 mg/day 10–20 mg/day IM	7 h	Oral capsule, oral suspension Injection
Lurasidone HCl (Latuda)	40–80 mg	18 h	Oral tablet

Conventional (Typical) Antipsychotics

Chlorpromazine	50–1200 mg/day	2–30 h	Oral tablet
Fluphenazine	2–20 mg/day	4.5–15.3 h	Oral elixir, oral tablet, injection
Fluphenazine decanoate	12.5–25 mg q3wk		Injection
Perphenazine	12–64 mg/day	Unknown	Oral tablet
Trifluoperazine	5–40 mg/day	47–10 h	Oral tablet
Thiothixene (Navane)	5–60 mg/day	3 h	Oral capsule
Loxapine (Adasuve)	10 mg/day	7 h	Oral inhalation with inhaler
Haloperidol (Haldol)	2–20 mg/day	21–2 h	Oral tablet, oral concentration, injection
Haloperidol decanoate (Haldol D)	50–100 mg q3wk	3 wk	Injection
Molindone	50–400 mg/day	1.5 h	Oral tablets

Pimozide 10 mg/day 55 h Oral tablets
(ORAP)

Note. IM = intramuscular.

TABLE 12.6 CYP450 METABOLISM OF COMMONLY USED ANTIPSYCHOTICS

Drug	How Metabolized	Induces Inhibits	
Aripiprazole	2D6, 3A4	None	None
Clozapine	1A2, 2C19, 2D6, 3A4	None	None
Haloperidol	1A2, 2D6, 3A4	None	2D6
Iloperidone	3A4, 2D6	None	3A
Lurasidone	3A4	None	None
	Eliminated in urine and feces		
Olanzapine	1A2, 2D6	None	None
Paliperidone	<10% 2D6, 3A4; primarily renal elimination	None	None
Quetiapine	3A4	None	None
Risperidone	2D6	None	Mild 2D6
Ziprasidone	1A2, 3A4	None	None

Note. Information based on Prescribing Information of each medication.

Excretion of these substances tends to be slow. Most antipsychotics have a half-life of 24 hours or longer, but many also have active metabolites with longer half-lives. These two effects make it difficult to predict elimination time, and metabolites of some of these agents may be found in the urine months later. When a medication is discontinued, the adverse reactions may not immediately subside. The patient may continue to experience and sometimes need treatment for the adverse reactions for several days. Similarly, patients who discontinue their antipsychotic drugs may still derive therapeutic benefit for several days to weeks after drug discontinuation.

High lipid solubility, accumulation in the body, and other factors have also made it difficult to correlate blood levels with therapeutic effects. [Table 12.5](#) shows the therapeutic ranges available for some of the antipsychotic medications. The potency of the antipsychotics also varies widely and is of specific concern when considering typical antipsychotic drugs.

Long-Acting Preparations

Currently, in the United States, atypical and conventional antipsychotics are available in long-acting forms. These antipsychotics are administered by injection once every 2 weeks to 3 months. Whereas the long-acting injectable atypical antipsychotics (risperidone, paliperidone, olanzapine, and aripiprazole) are water-based suspensions, the conventional antipsychotics are oil-based solutions. Long-acting injectable medications maintain a constant blood level between injections. Because they bypass problems with gastrointestinal absorption and first-pass metabolism, this method may enhance therapeutic outcomes for the patient. The use of these medications is expected to increase the likelihood of adhering to a prescribed medication regimen.

Nurses should be aware that the injection site may become sore and inflamed if certain precautions are not taken. The oil-based injections (fluphenazine and haloperidol) are viscous liquids. For these injections, a large gauge needle (at least 21 gauge) should be used. Because the medication is meant to remain in the injection site, the needle should be dry, and a deep IM injection should be given by the Z-track method. (Note: Do not massage the injection site. Rotate sites and document in the patient's record.) Manufacturer recommendations should be followed.

Side Effects, Adverse Reactions, and Toxicity

Various side effects and interactions can occur with antipsychotics, with the conventional (typical) antipsychotics producing different side effects than the atypical antipsychotics. The side effects vary largely based on their degree of attraction to different neurotransmitter receptors and their subtypes.

Cardiovascular Side Effects

Cardiovascular side effects include orthostatic hypotension and prolongation of the QTc interval (a marker indicating an abnormal electrocardiogram that could cause serious irregular heart rhythms). Orthostatic hypotension is very common and depends on the degree of blockade of α -adrenergic receptors. Typical and atypical antipsychotics have been associated with prolonged QTc intervals and

should be used cautiously in patients who have increased QTc intervals or are taking other medications that may prolong the QTc interval (Das et al., 2019). Other cardiovascular side effects from typical antipsychotics have been rare, but occasionally they cause ECG changes that have a benign or undetermined clinical effect.

Anticholinergic Side Effects

Anticholinergic side effects resulting from blockade of acetylcholine are another common side effect associated with antipsychotic drugs. Dry mouth, slowed gastric motility, constipation, urinary hesitancy or retention, vaginal dryness, blurred vision, dry eyes, nasal congestion, and confusion or decreased memory are examples of these side effects. Interventions for decreasing the impact of these side effects are outlined in [Table 12.1](#).

This group of side effects occurs with many of the medications used for psychiatric treatment. Using more than one medication with anticholinergic effects often increases the symptoms. Older patients are often most susceptible to a potential toxicity that results from high blockade of acetylcholine. This toxicity is called an *anticholinergic crisis* and is described more fully, along with its treatment, in [Chapter 24](#).

Weight Gain

Weight gain is a common side effect of the atypical antipsychotics, particularly clozapine and olanzapine (Zyprexa), which can cause a weight gain of up to 20 lb within 1 year. Ziprasidone (Geodon), aripiprazole (Abilify), and lurasidone (Latuda) are associated with little to no weight gain. If a patient becomes overweight or obese, switching to another antipsychotic should be considered and weight control interventions implemented.

Diabetes

One of the more serious side effects is the risk of type II diabetes. The FDA has determined that all atypical antipsychotics increase the risk for type II diabetes. Nurses should routinely assess for emerging symptoms of diabetes and alert the prescriber of these symptoms (see [Box 12.3](#)).

Sexual Side Effects

Sexual side effects result primarily from the blockade of dopamine in the tuberoinfundibular pathways of the hypothalamus. As a result, blood levels of prolactin may increase, particularly with risperidone and the typical antipsychotics. Increased prolactin causes breast enlargement and rare but potential galactorrhea (milk production and flow), decreased sexual drive, amenorrhea, menstrual irregularities, and increased risk for growth in preexisting breast cancers. Other sexual side effects include retrograde ejaculation (backward flow of semen), erectile dysfunction, and anorgasmia.

BOX 12.3

Recommended Assessments Before and During Antipsychotic Therapy

- Weigh all patients and track BMI during treatment.
- Determine if overweight (BMI 25–29.9) or obese (BMI ≥ 30).
- Monitor BMI monthly for first 3 months; then quarterly.
- Obtain baseline personal and family history of diabetes, obesity, dyslipidemia, hypertension, and cardiovascular disease.
- Get waist circumference (at umbilicus).
- Men: >40 in. (102 cm).
- Women: >35 in. (88 cm).
- Monitor BP, fasting plasma glucose, and fasting lipid profile within 3 months and then annually (more frequently for patients with diabetes or who have gained $>5\%$ of initial weight).
- Prediabetes (fasting plasma glucose 100–125 mg/dL).
- Diabetes (fasting plasma glucose >126 mg/dL).
- Hypertension (BP $>140/90$ mm Hg).
- Dyslipidemia (increased total cholesterol [>200 mg], decreased HDL, and increased LDL).

BMI, body mass index; BP, blood pressure; HDL, high-density lipoprotein; LDL, low-density lipoprotein.

Blood Disorders

Blood dyscrasias are rare but have received renewed attention since the introduction of clozapine (Clozaril). Agranulocytosis is an acute reaction that causes the individual's white blood cell count to drop to very low levels often related to neutropenia, a drop in neutrophils. In the case of the antipsychotics, the medication suppresses the bone marrow precursors to blood factors. The exact mechanism by which the drugs produce this effect is unknown. The most

notable symptoms of this disorder include high fever, sore throat, and mouth sores. Although benign elevations in temperature have been reported in individuals taking clozapine, no fever should go uninvestigated. Untreated neutropenia can be life threatening. Although severe neutropenia can occur with any of the antipsychotics, the risk with clozapine is greater than with the other antipsychotics. Therefore, prescription of clozapine requires weekly blood samples for the first 6 months of treatment and then every 2 weeks after that for as long as the drug is taken. Drawing of these samples must continue for 4 weeks after clozapine use has been discontinued. If sore throat or fever develops, medications should be withheld until a leukocyte count can be obtained. Hospitalization, including reverse isolation to prevent infections, is usually required. Severe neutropenia is more likely to develop during the first 18 weeks of treatment (Novartis, 2020).

Neuroleptic Malignant Syndrome

Neuroleptic malignant syndrome (NMS) is a serious complication that may result from antipsychotic medications. Characterized by rigidity and high fever, NMS is a rare condition that may occur abruptly with even one dose of medication. Temperature must always be monitored when administering antipsychotics, especially high-potency medications. This condition is discussed more fully in [Chapter 24](#).

Other Side Effects

Photosensitivity reactions to antipsychotics, including severe sunburns or rash, most commonly develop with the use of low-potency typical medications. Sun block must be worn on all areas of exposed skin when taking these drugs. In addition, sun exposure may cause pigmentary deposits to develop, resulting in discoloration of exposed areas, especially the neck and face. This discoloration may progress from a deep orange color to a blue gray. Skin exposure should be limited, and skin tone changes reported to the prescriber. Pigmentary deposits, retinitis pigmentosa, may also develop on the retina of the eye.

Antipsychotics may also lower the seizure threshold. Patients with an undetected seizure disorder may experience seizures early in treatment. Those who have a preexisting condition should be monitored closely.

Medication-Related Movement Disorders

Medication-related movement disorders are side effects or adverse reactions that are commonly caused by typical antipsychotic medications but less commonly with atypical antipsychotic drugs. These disorders of abnormal motor movements can be divided into two groups: acute **extrapyramidal symptoms (EPS)**, which develop early in the course of treatment (sometimes after just one dose), and chronic syndromes, which develop from longer exposure to antipsychotic drugs.

Acute Extrapyramidal Symptoms

Acute EPS are acute abnormal movements that include dystonia, pseudoparkinsonism, and akathisia. They develop early in treatment, sometimes from as little as one dose. Although the abnormal movements are treatable, they are at times dramatic and frightening, causing physical and emotional impairments that often prompt patients to stop taking their medication. EPS occur when there is an imbalance of acetylcholine, dopamine, and GABA in the basal ganglia because of blocking dopamine.

Dystonia, sometimes referred to as an *acute dystonic reaction*, is impaired muscle tone that generally is the first EPS to occur, usually within a few days of initiating use of an antipsychotic. Acetylcholine is overactive because one of its modulators, dopamine, is blocked. Dystonia is characterized by involuntary muscle spasms that lead to abnormal postures especially of the head and neck muscles. Acute dystonia occurs most often in young men, adolescents, and children. Patients usually first report a thick tongue, tight jaw, or stiff neck. Dystonia can progress to a protruding tongue, oculogyric crisis (eyes rolled up in the head), torticollis (muscle stiffness in the neck, which draws the head to one side with the chin pointing to the other), and laryngopharyngeal constriction. Abnormal postures of the upper limbs and torso may be held briefly or sustained. In severe cases, the spasms may progress to the intercostal muscles, producing more significant breathing difficulty for patients who already have respiratory impairment from asthma or emphysema. The treatment is the administration of a medication such as the anticholinergic agents that inhibit acetylcholine and thereby restore the balance of neurotransmitters ([Table 12.7](#)).

Drug-induced parkinsonism is sometimes referred to as **pseudoparkinsonism** because its presentation is identical to Parkinson disease. The difference is that

the activity of dopamine is blocked in pseudoparkinsonism, and in Parkinson disease, the cells of the basal ganglia are destroyed. Older patients are at the greatest risk for experiencing pseudoparkinsonism (Factor et al., 2020). Symptoms include the classic triad of rigidity, slowed movements (akinesia), and tremor. The rigid muscle stiffness is usually seen in the arms. Akinesia can be observed by the loss of spontaneous movements, such as the absence of the usual relaxed swing of the arms while walking. In addition, mask-like facies or loss of facial expression and a decrease in the ability to initiate movements also are present. Usually, tremor is more pronounced at rest, but it can also be observed with intentional movements, such as eating. If the tremor becomes severe, it may interfere with the patient's ability to eat or maintain adequate fluid intake. Hypersalivation is possible as well. Pseudoparkinsonism symptoms may occur on one or both sides of the body and develop abruptly or subtly but usually within the first 30 days of treatment. The treatment is the reduction in dosage or a change of antipsychotic that has less affinity for the dopamine receptor. Anticholinergic medication is sometimes given.

Akathisia is characterized by an inability to sit still or restlessness and is more common in middle-aged patients. The person will pace, rock while sitting or standing, march in place, or cross and uncross the legs. All these repetitive motions have an intensity that is frequently beyond the explanation of the individual. In addition, akathisia may be present as a primarily subjective experience without obvious motor behavior. This subjective experience includes feelings of anxiety, jitteriness, or the inability to relax, which the individual may or may not be able to communicate. It is extremely uncomfortable for a person experiencing akathisia to be forced to sit still or be confined. These symptoms are sometimes misdiagnosed as agitation or an increase in psychotic symptoms. If an antipsychotic medication is given, the symptoms will not abate and will often worsen. Differentiating akathisia from agitation may be aided by knowing the person's symptoms before the introduction of medication. Whereas psychotic agitation does not usually begin abruptly after antipsychotic medication use has been started, akathisia may occur after administration. In addition, the nurse may ask the patient if the experience is felt primarily in the muscles (akathisia) or in the mind or emotions (agitation).

TABLE 12.7 DRUG THERAPIES FOR ACUTE MEDICATION-RELATED MOVEMENT

DISORDERS

Agents	Typical Dosage Ranges	Routes Available	Common Side Effects
Anticholinergics			
Benztropine (Cogentin)	2–6 mg/day	PO, IM, IV	Dry mouth, blurred vision, slowed gastric motility causing constipation, urinary retention, increased intraocular pressure; overdose produces toxic psychosis.
Trihexyphenidyl (Artane)	4–15 mg/day	PO	Same as benztropine, plus gastrointestinal distress. Older adults are most prone to mental confusion and delirium.
Biperiden (Akineton)	2–8 mg/day	PO	Fewer peripheral anticholinergic effects. Euphoria and increased tremor may occur.
Antihistamines			
Diphenhydramine (Benadryl)	25–50 mg QID to 400 mg daily	PO, IM, IV	Sedation and confusion, especially in older adults.
Dopamine Agonists			
Amantadine (Symmetrel)	100–400 mg daily	PO	Indigestion, decreased concentration, dizziness, anxiety, ataxia, insomnia, lethargy, tremors, and slurred speech may occur with higher doses. Tolerance may develop on fixed dose.
α-Blockers			
Propranolol (Inderal)	10 mg TID to 120 mg daily	PO	Hypotension and bradycardia. Must monitor pulse and blood pressure. Do not stop abruptly because doing so may cause rebound tachycardia.
Benzodiazepines			
Lorazepam (Ativan)	1–2 mg IM		

	0.5–2 mg	PO, IM PO	All may cause drowsiness, lethargy, and general sedation or paradoxical agitation. Confusion and disorientation in older adults.
Diazepam (Valium)	2–5 mg TID	PO, IV	Most side effects are rare and will disappear if dose is decreased.
Clonazepam (Klonopin)	1–4 mg/day	PO	Tolerance and withdrawal are potential problems.

Note. IM = intramuscular; IV = intravenous.

Akathisia is the most difficult acute medication-related movement disorder to relieve. It does not usually respond well to anticholinergic medications. Rapid initiation of antipsychotics can increase the onset of akathisia (Yoshimura et al., 2018). The pathology of akathisia may involve more than just the extrapyramidal motor system. It may include serotonin changes that also affect the dopamine system. The usual approach to treatment is to change or reduce the antipsychotic. Several medications are used to reduce symptoms, including β -adrenergic blockers, anticholinergics, antihistamines, and low-dose antianxiety agents with limited success. Frequently, combinations of these medication are used (Poyurovsky & Weizman, 2020).

Several nursing interventions reduce the impact of these syndromes. Individuals with acute EPS need frequent reassurance that this is not a worsening of their psychiatric condition but instead is a treatable side effect of the medication. They also need validation that what they are experiencing is real and that the nurse is concerned and will be responsive to changes in these symptoms. Physical and psychological stress appears to increase the symptoms and further frighten the patient; therefore, decreasing stressful situations becomes important. These symptoms are often physically exhausting for the patient, and the nurse should ensure that the patient receives adequate rest and hydration. Because tremors, muscle rigidity, and motor restlessness may interfere with the individual's ability to eat, the nurse may need to assist the patient with eating and drinking fluids to maintain nutrition and hydration.

Risk factors for acute EPS include previous episodes of EPS. The nurse should listen closely when patients say they are “allergic” or have had “bad reactions” to antipsychotic medications. Often, they are describing one of the medication-related movement disorders, particularly dystonia, rather than a rash or other allergic symptom.

Chronic Syndromes: Tardive Dyskinesia

Chronic syndromes develop from long-term use of antipsychotics. They are serious and affect about 20% of the patients who receive typical antipsychotics for an extended period. These conditions are typically irreversible and cause significant impairment in self-image, social interactions, and occupational functioning. Early symptoms and mild forms may go unnoticed by the person experiencing them.

Tardive dyskinesia, the most well-known of the chronic syndromes, involves irregular, repetitive involuntary movements of the mouth, face, and tongue, including chewing, tongue protrusion, lip smacking, puckering of the lips, and rapid eye blinking. Abnormal finger movements are common as well. In some individuals, the trunk and extremities are also involved, and in rare cases, irregular breathing and swallowing lead to belching and grunting noises. These symptoms usually begin no earlier than after 6 months of treatment or when the medication is reduced or withdrawn. Once thought to be irreversible, considerable controversy now exists as to whether this is true.

The risk for experiencing tardive dyskinesia increases with age. Although the prevalence of tardive dyskinesia averages 15% to 20%, the rate rises to 50% to 70% in older patients receiving antipsychotic medications. The risk of probable tardive dyskinesia is three times lower in older adults receiving atypical antipsychotics compared to conventional antipsychotics (O'Brien, 2016). Women are at higher risk than men. Anyone receiving antipsychotic medication can develop tardive dyskinesia. Risk factors are summarized in [Box 12.4](#). The causes of tardive dyskinesia remain unclear, but the most widely accepted theory is that dopamine antagonists block dopamine receptors, and evidence does suggest that imbalances of other neurotransmitters may be involved (Cornett et al., 2017).

BOX 12.4

Risk Factors for Tardive Dyskinesia

- Age older than 50 years
- Female
- Affective disorders, particularly depression
- Brain damage or dysfunction
- Increased duration of treatment

- Standard antipsychotic medication
- Possible higher doses of antipsychotic medication

Two medications recently approved by the FDA have shown promising results. Valbenazine (INGREZZA), a vesicular monoamine transporter 2 (VAMT2), was approved for the treatment of tardive dyskinesia. A related medication, deutetrabenazine (AUSTEDO), has a longer half-life than valbenazine, but twice-daily dosing with food is recommended (Citrome, 2020). Dietary precursors of acetylcholine, such as lecithin and vitamin E supplements, may prove to be beneficial.

The best approach to treatment remains avoiding the development of the chronic syndromes. Preventive measures include use of atypical antipsychotics, using the lowest possible dose of typical medication, minimizing use of as-needed (PRN) medication, and closely monitoring individuals in high-risk groups for development of the symptoms of tardive dyskinesia. All members of the mental health treatment team who have contact with individuals taking antipsychotics for longer than 3 months must be alert to the risk factors and earliest possible signs of chronic medication-related movement disorders.

Monitoring tools, such as the Abnormal Involuntary Movement Scale (see Appendix B), should be used routinely to standardize assessment and provide the earliest possible recognition of the symptoms. Standardized assessments should be performed at a minimum of 3- to 6-month intervals. The earlier the symptoms are recognized, the more likely they will resolve if the medication can be changed or its use discontinued. Newer, atypical antipsychotic medications have a much lower risk of causing tardive dyskinesia and are increasingly being considered first-line medications for treating patients with schizophrenia. Other medications are under development to provide alternatives that limit the risk for tardive dyskinesia.

Mood Stabilizers (Antimanic Medications)

Mood stabilizers, or antimanic medications, are psychopharmacologic agents used primarily for stabilizing mood swings, particularly those of mania in bipolar disorders. Lithium, the oldest, is the gold standard of treatment for acute mania and maintenance of bipolar disorders. Not all respond to lithium, and increasingly, other drugs are being used as first-line agents. Anticonvulsants, calcium channel blockers, adrenergic blocking agents, and atypical

antipsychotics are used for mood stabilization.

Lithium

Lithium, a naturally occurring element, is effective in about 40% of patients with bipolar disorder. Although lithium is not a perfect drug, a great deal is known regarding its use—it is inexpensive, it has restored stability to the lives of thousands of people, and it remains the gold standard of bipolar pharmacologic treatment.

Indications and Mechanisms of Action

Lithium is indicated for symptoms of mania characterized by rapid speech, flight of ideas (jumping from topic to topic), irritability, grandiose thinking, impulsiveness, and agitation. Because it has mild antidepressant effects, lithium is used in treating depressive episodes of bipolar illness. It is also used as augmentation in patients experiencing major depression that has only partially responded to antidepressants alone. Lithium also has been shown to be helpful in reducing impulsivity and aggression in certain psychiatric patients.

The exact action by which lithium improves the symptoms of mania is unknown, but it is thought to exert multiple neurotransmitter effects, including enhancing serotonergic transmission, increasing synthesis of norepinephrine, and blocking postsynaptic dopamine. It has also been suggested that lithium's mood-stabilizing effects are related to the fact that it acts on cellular targets and exerting neuroprotective effects (Van Gestel et al., 2019).

Lithium is actively transported across cell membranes, altering sodium transport in both nerve and muscle cells. It replaces sodium in the sodium–potassium pump and is retained more readily than sodium inside the cells. Conditions that alter sodium content in the body, such as vomiting, diuresis, and diaphoresis, also alter lithium retention. The results of lithium influx into the nerve cell lead to increased storage of catecholamines within the cell, reduced dopamine neurotransmission, increased norepinephrine reuptake, increased GABA activity, and increased serotonin receptor sensitivity. Lithium also alters the distribution of calcium and magnesium ions and inhibits second messenger systems within the neuron. The mechanisms by which lithium improves the symptoms of mania are complex and interrelated, involving the sum of all or part

of these actions and more.

Pharmacokinetics

Lithium carbonate is available orally in capsule, tablet, and liquid forms. Slow-release preparations are also available. Lithium is readily absorbed in the gastric system and may be taken with food, which does not impair absorption. Peak blood levels are reached in 1 to 4 hours, and the medication is usually completely absorbed in 8 hours. Slow-release preparations are absorbed at a slower, more variable rate.

Lithium is not protein bound, and its distribution into the CNS across the blood–brain barrier is slow. The onset of action is usually 5 to 7 days and may take as long as 2 weeks. The elimination half-life is 8 to 12 hours and is 18 to 36 hours in individuals whose blood levels have reached steady state and whose symptoms are stable. Lithium is almost entirely excreted by the kidneys but is present in all body fluids. Conditions of renal impairment or decreased renal function in older patients decrease lithium clearance and may lead to toxicity. Several medications affect renal function and therefore change lithium clearance. See Chapter 26 for a list of these and other medication interactions with lithium. About 80% of lithium is reabsorbed in the proximal tubule of the kidney along with water and sodium. In conditions that cause sodium depletion, such as dehydration caused by fever, strenuous exercise, hot weather, increased perspiration, and vomiting, the kidneys attempt to conserve sodium. Because lithium is a salt, the kidneys retain lithium as well, leading to increased blood levels and potential toxicity. Significantly increasing sodium intake causes lithium levels to fall.

Lithium is usually administered in doses of 300 mg two to three times daily. Because it is a drug with a narrow therapeutic range or index, blood levels are monitored frequently during acute mania, and the dosage is increased every 3 to 5 days. These increases may be slower in older adult patients or patients who experience uncomfortable side effects. Blood levels should be monitored 12 hours after the last dose of medication. In the hospital setting, nurses should withhold the morning dose of lithium until the serum sample is drawn to avoid falsely elevated levels. Individuals who are at home should be instructed to have their blood drawn in the morning about 12 hours after their last dose and before they take their first dose of medication. During the acute phases of mania, blood levels of 0.8 to 1.4 mEq/L are usually attained and maintained until symptoms

are under control. The therapeutic range for lithium is narrow, and patients in the higher end of that range usually experience more uncomfortable side effects. During maintenance, the dosage is reduced, and dosages are adjusted to maintain blood levels of 0.4 to 1 mEq/L.

Lithium clears the body relatively quickly after discontinuation of its use. Withdrawal symptoms are rare, but occasional anxiety and emotional lability have been reported. It is important to remember that almost half of the individuals who discontinue lithium treatment abruptly experience a relapse of symptoms within a few weeks. Some research suggests that if a person stops taking lithium, the drug will be less effective when the medication is restarted. Patients should be warned of the risks in abruptly discontinuing their medication and should be advised to consider the options carefully in consultation with their prescriber.

Side Effects, Adverse Reactions, and Toxicity

At lower therapeutic blood levels, side effects from lithium are relatively mild. These reactions correspond with peaks in plasma concentrations of the medication after administration and most subside during the first few weeks of therapy. Frequently, individuals taking lithium complain of excessive thirst and an unpleasant metallic-like taste. Sugarless throat lozenges may be useful in minimizing this side effect. Other common side effects include increased frequency of urination, fine head tremor, drowsiness, and mild diarrhea. Weight gain occurs in about 20% of the individuals taking lithium. Nausea may be minimized by taking the medication with food or by use of a slow-release preparation. However, slow-release forms of lithium increase diarrhea. Muscle weakness, restlessness, headache, acne, rashes, and exacerbation of psoriasis have also been reported. See Chapter 26 for a summary of selected nursing interventions to minimize the impact of common side effects associated with lithium treatment. Patients most frequently discontinued their own medication use because of concerns with mental slowness, poor concentration, and memory problems.

As blood levels of lithium increase, the side effects of lithium become more numerous and severe. Early signs of lithium toxicity include severe diarrhea, vomiting, drowsiness, muscular weakness, and lack of coordination. Lithium should be withheld, and the prescriber consulted if these symptoms develop. Lithium toxicity can easily be resolved in 24 to 48 hours by discontinuing the

medication, but hemodialysis may be required in severe situations. See Chapter 26 for a summary of the side effects and symptoms of toxicity associated with various blood levels of lithium.

Monitoring of creatinine concentration, thyroid hormones, and CBC every 6 months during maintenance therapy helps to assess the occurrence of other potential adverse reactions. Kidney damage is considered an uncommon but potentially serious risk of long-term lithium treatment. This damage is usually reversible after discontinuation of the lithium use. A gradual rise in serum creatinine and decline in creatinine clearance indicate the development of renal dysfunction. Individuals with preexisting kidney dysfunction are susceptible to lithium toxicity.

Lithium may alter thyroid function, usually after 6 to 18 months of treatment. About 30% of the individuals taking lithium exhibit elevations in thyroid-stimulating hormone, but most do not show suppression of circulating thyroid hormone. Thyroid dysfunction from lithium treatment is more common in women, and some individuals require the addition of thyroxine to their care. During maintenance, thyroid-stimulating hormone levels may be monitored. Nurses should observe for dry skin, constipation, bradycardia, hair loss, cold intolerance, and other symptoms of hypothyroidism. Other endocrine system effects result from hypoparathyroidism, which increases parathyroid hormone levels and calcium. Clinically, this change is not significant, but elevated calcium levels may cause mood changes, anxiety, lethargy, and sleep disturbances. These symptoms may erroneously be attributed to depression if hypercalcemia is not investigated.

Lithium use must be avoided during pregnancy because it has been associated with birth defects, especially when administered during the first trimester. If lithium is given during the third trimester, toxicity may develop in a newborn, producing signs of hypotonia, cyanosis, bradykinesia, cardiac changes, gastrointestinal bleeding, and shock. Diabetes insipidus may persist for months. Lithium is also present in breast milk, and women should not breastfeed while taking lithium. Women expecting to become pregnant should be advised to consult with a physician before discontinuing use of birth control methods.

Anticonvulsants

In the psychiatric–mental health area, anticonvulsants are commonly used to

treat patients with bipolar disorder and are considered mood stabilizers. The following discussion highlights the use of anticonvulsants as mood stabilizers in the treatment of bipolar disorder.

Indications and Mechanisms of Action

Valproate (valproic acid; Depakote), carbamazepine (Equetro), and lamotrigine (Lamictal) have FDA approval for the treatment of bipolar disorder, mania, or mixed episodes (see Chapter 26). In general, the anticonvulsant mood stabilizers have many actions, but their effects on ion channels, reducing repetitive firing of action potentials in the nerves, most directly decrease manic symptoms. No one action has successfully accounted for the anticonvulsants' ability to stabilize mood (Landgraf et al., 2016).

Pharmacokinetics

Valproic acid is rapidly absorbed, but the enteric coating of divalproex sodium adds a delay of as long as 1 hour. Peak serum levels occur in about 1 to 4 hours. The liquid form (sodium valproate) is absorbed more rapidly and peaks in 15 minutes to 2 hours. Food appears to slow absorption but does not lower bioavailability of the drug.

Carbamazepine is absorbed in a somewhat variable manner. The liquid suspension is absorbed more quickly than the tablet form, but food does not appear to interfere with absorption. Peak plasma levels occur in 2 to 6 hours. Because high doses influence peak plasma levels and increase the risk for side effects, carbamazepine should be given in divided doses two or three times a day. The suspension, which has higher peak plasma levels and lower trough levels, must be given more frequently than the tablet form.

These medications cross easily into the CNS, move into the placenta as well, and are associated with an increased risk for birth defects. Carbamazepine, valproic acid, and lamotrigine are metabolized by the CYP450 system. However, one of the metabolites of carbamazepine is potentially toxic. If other concurrent medications inhibit the enzymes that break down this toxic metabolite, severe adverse reactions are often the result. Medications that inhibit this breakdown include erythromycin, verapamil, and cimetidine (now available in nonprescription form).

Teaching Points

Nurses need to educate patients about potential drug interactions, especially with nonprescription medications. Nurses can also inform other health care practitioners who may be prescribing medication that these patients are taking carbamazepine. It is important to note that oral contraceptives may become ineffective, and female patients should be advised to use other methods of birth control.

Side Effects, Adverse Reactions, and Toxicity of Anticonvulsants

The most common side effects of carbamazepine are dizziness, drowsiness, tremor, visual disturbance, nausea, and vomiting. These side effects may be minimized by initiating treatment in low doses. Patients should be advised that these symptoms will diminish, but care should be taken when changing positions or performing tasks that require visual alertness. Giving the drug with food may diminish nausea. Adverse reactions include rare aplastic anemia, agranulocytosis, severe rash, rare cardiac problems, and syndrome of inappropriate secretion of the diuretic hormone caused by hyponatremia.

Valproic acid also causes gastrointestinal disturbances, tremor, and lethargy. In addition, it can produce weight gain and alopecia (hair loss). These symptoms are transient and should diminish with the course of treatment. Dietary supplements of zinc and selenium may be helpful to patients experiencing hair loss. Constipation and urinary retention occur in some individuals. Nurses should monitor urinary output and assist patients to increase fluid consumption to decrease constipation.

Benign skin rash, sedation, blurred or double vision, dizziness, nausea, vomiting, and other gastrointestinal symptoms are side effects of lamotrigine. In rare cases, lamotrigine (Lamictal) produces severe, life-threatening rashes that usually occur within 2 to 8 weeks of treatment. This risk is highest in children. Use of lamotrigine should be immediately discontinued if a rash is noted.

Transient elevations in liver enzymes occur with both carbamazepine and valproic acid but symptoms of hepatic injury rarely occur. If the patient reports abnormal pain or shows signs of jaundice, the prescriber should be notified immediately. Several blood dyscrasias are associated with carbamazepine, including aplastic anemia, agranulocytosis, and leukopenia. Patients should be

advised to report fever, sore throat, rash, petechiae, or bruising immediately. In addition, patients should be advised of the importance of completing routine blood tests throughout treatment. The risks for aplastic anemia and agranulocytosis with carbamazepine use still require close monitoring of CBCs during treatment. Valproate and its derivatives have had a similar course of development.

Antidepressant Medications

Medications classified as antidepressants are used not only for the treatment of depression but also in the treatment of anxiety disorders, eating disorders, and other mental health states (Table 12.8). They are used very cautiously in persons with bipolar disorder because of the possibility of precipitating a manic episode. The exact neuromechanism for the antidepressant effect is unknown in all of them. The onset of action also varies considerably and appears to depend on factors outside of steady-state plasma levels. Initial improvement with some antidepressants, such as the SSRIs, may appear within 7 days, but complete relief of symptoms may take several weeks. Antidepressants should not be discontinued abruptly because of uncomfortable symptoms that result. Discontinuance of use of these medications requires slow tapering. Individuals taking these medications should be cautioned not to abruptly stop using them without consulting their prescriber. Antidepressant medications are well absorbed from the gastrointestinal system; however, some individual variations exist. Most of the antidepressants are metabolized by liver enzymes so that other drugs metabolized by these enzymes may increase or decrease blood levels of the antidepressants (see Table 12.9). All these medications have a “boxed warning” for increased risk of suicidal behavior in children, adolescents, and young adults.

TABLE 12.8 ANTIDEPRESSANT MEDICATIONS

Generic (Trade) Drug Name	Usual Dosage Range (mg/day)	Therapeutic Blood Level Half-Life (h) (ng/mL)
------------------------------	--------------------------------	---

Selective Serotonin Reuptake Inhibitors

Citalopram (Celexa)	20–50	35	Not available
Escitalopram (Lexapro)	10–20	27–32	Not available
Fluoxetine (Prozac)	20–80	2–9 days	72–300
Fluvoxamine (Luvox)	50–300	17–22	Not available
Paroxetine (Paxil)	10–50	10–24	Not available
Sertraline (Zoloft)	50–200	24	Not available

Serotonin Norepinephrine Reuptake Inhibitors

Desvenlafaxine (Pristiq Extended Release)	50	11	Not available
Duloxetine (Cymbalta)	40–60	8–17	Not available
Levomilnacipran (Fetzima)	40–120	12	Not available
Nefazodone	100–600	2–4	Not available
Venlafaxine (Effexor)	75–375	5–11	100–500

Norepinephrine Dopamine Reuptake Inhibitor

Bupropion (Wellbutrin)	200–450	8–24	10–29
---------------------------	---------	------	-------

α2 blocker-Antagonist

Mirtazapine (Remeron)	15–45	20–40	Not available
--------------------------	-------	-------	---------------

NMDA Antagonist

Esketamine (Spravato)	56–84 titrated from twice a week to every other week	2–12 hours	Not available
--------------------------	--	------------	---------------

Others

Trazodone (Desyrel)	150–600	4–9	650–1600
Vilazodone (Viibryd)	10–40	25	Not available
Vortioxetine (Brintellix)	5–20	66	Not available

Tricyclic Antidepressants			
Amitriptyline (Elavil)	50–300	31–46	110–250
Amoxapine	50–600	8	200–500
Clomipramine (Anafranil)	25–250	19–37	80–100
Imipramine (Tofranil)	30–300	11–25	200–350
Desipramine (Norpramin)	25–300	12–24	125–300
Doxepin	25–300	8–24	100–200
Nortriptyline (Aventyl, Pamelor)	30–100	18–44	50–150
Protriptyline (Vivactil)	15–60	67–89	100–200
Tetracyclic			
Maprotiline (Ludiomil)	50–225	21–25	200–300
Monoamine Oxidase Inhibitors			
Isocarboxazid (Marplan)	20–60	Not available	Not available
Phenelzine (Nardil)	15–90	24 (effect lasts 3–4 days)	Not available
Tranylcypromine (Parnate)	10–60	24 (effect lasts 3–10 days)	Not available
Selegiline (Emsam)	6–12 mg/24 h	25%–50% delivered in 24 h	Not available

Note. IM = intramuscular; IV = intravenous; NMDA = N-methyl D-aspartate.

TABLE 12.9 CYP450 METABOLISM OF COMMON ANTIDEPRESSANTS

Drug	How Metabolized	Induces	Inhibits
-------------	------------------------	----------------	-----------------

Bupropion	2B6	None	2D6
Citalopram	2C19, 2D6, 3A4	None	Mild 2D6
Desvenlafaxine	3A4	None	Mild 2D6
Duloxetine	1A2, 2D6	None	2D6
Escitalopram	2C19, 2D6, 3A4	None	Mild 2D6
Esketamine	2B6, 3A4, 2C9, 2C19	2B	3A4, 2D1
Fluoxetine	2C9, 2C19, 2D6, 3A4	None	2C19, 2D6 3A4, norfluoxetine
Fluvoxamine	1A2, 2D6	None	1A2, 2C9, 2C19, 3A4
Mirtazapine	1A2, 2D6, 3A4	None	None
Nefazodone	2D6, 3A4	None	3A4
Paroxetine	2D6	None	2D6, 2B6
Selegiline	2A6, 2C9, 3A4/5	None	2D6, 3A4/5
Sertraline	2B6, 2C9, 2D6, 3A4	None	2B6, 2C9, 2C19, 2D6, 3A4 (dosage >200 mg)
St. John's Wort*	3A4	3A4	None
Trazodone	2D6, 3A4	None	None
Tricyclic antidepressants	2D6, others depending on drug	None	Mild 2D6
Venlafaxine	2D6	None	Mild 2D6
Vilazodone	3A4, 2C19, 2D6	None	2C8
Vortioxetine	2D6, 3A4/5, 2C9, 2A6, None 2C8, 2B6	None	None

* Not a U.S. Food and Drug Administration–approved antidepressant.

Note. Information from the Prescribing Information of each medication.

Serotonin syndrome, or serotonin intoxication syndrome, can occur if there is an overactivity of serotonin or an impairment of the serotonin metabolism. Concomitant medications such as triptans used to treat migraines also can increase the serotonergic activity. With the advent of widely used antidepressants targeting the serotonergic systems, symptoms of this serious side effect should be assessed. Symptoms include mental status changes (hallucinations, agitation, coma), autonomic instability (tachycardia, hyperthermia, changes in blood pressure), neuromuscular problems (hyperreflexia, incoordination), and gastrointestinal disturbance (nausea, vomiting, diarrhea). Serotonin syndrome can be life threatening. The treatment for serotonin syndrome is discontinuation of the medication and symptom management.

Selective Serotonin Reuptake Inhibitors

The serotonergic system is associated with mood, emotion, sleep, and appetite and is implicated in the control of numerous emotional, physical, and behavioral functions (see [Chapter 8](#)). Decreased serotonergic neurotransmission has been proposed to play a key role in depression. In 1988, fluoxetine (Prozac) was the first of a class of drugs that acted “selectively” on serotonin, one group of neurotransmitters associated with depression. Other similarly selective medications, sertraline (Zoloft), paroxetine (Paxil), and fluvoxamine (Luvox), soon followed. The newest SSRI is escitalopram oxalate (Lexapro).

All the SSRIs inhibit the reuptake of serotonin by blocking its transport into the presynaptic neuron, which in turn increases the concentration of synaptic serotonin. The concentration of synaptic serotonin is controlled directly by its reuptake; thus, drugs blocking serotonin transport have been successfully used for the treatment of depression and other conditions associated with serotonergic activity.

The SSRIs also have other properties that account for the common side effects, which include headache, anxiety, insomnia, transient nausea, vomiting, and diarrhea. Sedation may also occur, especially with paroxetine. Most often, these medications are given in the morning, but if daytime sedation occurs, they may be given in the evening. Higher doses, especially of fluoxetine, are more likely to produce sedation. Nausea and dizziness are common side effects which may subside within a few weeks. These side effects, along with sexual dysfunction, sedation, diastolic hypertension, and increased perspiration, tend to be dose dependent, occurring more frequently at higher doses. Other common side effects include insomnia, constipation, dry mouth, tremors, blurred vision, and asthenia or muscle weakness.

Sexual dysfunction is a relatively common side effect with most antidepressants. Erectile and ejaculation disturbances occur in men and anorgasmia in women. This side effect is often difficult to assess if the nurse has not obtained a sexual history before initiation of use of the medication. Anorgasmia is particularly common with the SSRIs and often goes unreported, frequently because nurses and other health care providers do not ask.

Serotonin Norepinephrine Reuptake Inhibitors

Decreased activity of the neurotransmitter norepinephrine is also associated with depression and anxiety disorders. Venlafaxine (Effexor), nefazodone, duloxetine (Cymbalta), and desvenlafaxine (Pristiq) prevent the reuptake of both serotonin and norepinephrine at the presynaptic site and are classified as serotonin norepinephrine reuptake inhibitors (SNRIs). Desipramine (Norpramin) is technically a tricyclic antidepressant (TCA) and is usually categorized as such. It works, however, on both serotonin and norepinephrine, so it can also be considered an SNRI.

The side effects are like those of the SSRIs; there is also a risk for an associated increase in blood pressure. Elevations in blood pressure have been described, and nurses should monitor blood pressure, especially in patients who have a history of hypertension. Venlafaxine (Effexor) has little effect on acetylcholine and histamine; thus, it creates only mild sedation and anticholinergic symptoms. This medication is often used if a depressed patient is sleeping excessively and reports little energy. The most common side effects of nefazodone (Serzone) include dry mouth, nausea, dizziness, muscle weakness, constipation, and tremor. It is unlikely to cause sexual disturbance. Nefazodone also has a “boxed warning” for hepatic failure and should not be used in those with acute liver disease.

Norepinephrine Dopamine Reuptake Inhibitors

Bupropion (Wellbutrin, Zyban) inhibits reuptake of norepinephrine, serotonin, and dopamine. Wellbutrin is indicated for depression and Zyban for nicotine addiction. The smoking cessation medication, Zyban, is given at a lower dose than Wellbutrin. Patients should not take Zyban if they are taking Wellbutrin. Bupropion has a chemical structure unlike any of the other antidepressants and somewhat resembles a few of the psychostimulants. Bupropion’s activating effects may be experienced as agitation or anxiety by some patients. Others also experience insomnia and appetite suppression. For a few individuals, bupropion has produced psychosis, including hallucinations and delusions. Most likely, this is secondary to overstimulation of the dopamine system. Bupropion is contraindicated for people with seizure disorders and those at risk for seizures. The rate of seizures is similar to that with the SSRIs and mirtazapine but is lower than the rate associated with the older antidepressants. Most importantly, bupropion has a lower incidence of sexual dysfunction and often is used in

individuals who are experiencing these side effects with other antidepressants (GlaxoSmithKline, 2019; Montejo et al., 2019).

α_2 -Antagonist

Mirtazapine (Remeron) boosts norepinephrine or noradrenaline and serotonin by blocking α_2 -adrenergic presynaptic receptors on a serotonin receptor (5-HT_{2A}, 5-HT_{2C}, 5-HT₃). This is a different action than the other antidepressants. A histamine receptor is also blocked, which may explain its sedative side effect. Mirtazapine is indicated for depression. Side effects include sedation (at lower doses), dizziness, weight gain, dry mouth, constipation, and change in urinary functioning.

N-methyl D-aspartate Receptor Antagonist

In March 2019, the FDA approved a nasal spray formulation of esketamine (Spravato) for treatment resistant depression. Esketamine is a similar formulation to ketamine, an FDA-approved anesthetic. Esketamine is not approved as an anesthetic agent and ketamine is not approved for the treatment of depression, but it has been used off-label for rapid relief of severe depression. Ketamine also produces euphoria, dissociation, and hallucinations, has a high risk of abuse, and is a well-known street drug, Special K (see Chapter 31).

Esketamine is a nonselective, noncompetitive antagonist of N-methyl D-aspartate receptor, blocking glutamate. Esketamine reaches maximum plasma concentration in 20 to 24 minutes. Once administered, there is a rapid decline in plasma concentration within 4 to 8 hours. It is metabolized primarily in the liver and excreted in the urine (Dinis-Oliveira, 2017; Janssen Pharmaceutical Companies, 2019).

Esketamine is given under direct supervision of a health care provider. The FDA recommends that esketamine be given in conjunction with an oral antidepressant. A treatment session consists of a nasal administration and post-administration observation. Blood pressure is assessed before and after treatment. The medication is given in two phases. During the induction phase (weeks 1–4), the medication is given twice a week; during maintenance phase

(weeks 5–8), esketamine is given weekly, and after 9 weeks, it is given every 2 weeks. The medication has a boxed warning for sedation, dissociation, abuse and misuse, and suicidal thoughts and behavior. Other side effects include increase in blood pressure, short- and long-term cognitive impairment, impaired ability to drive and operate machinery, ulcerative or interstitial cystitis, and embryo–fetal toxicity (Gastaldon et al., 2020, Janssen Pharmaceutical Companies, 2019). Due to the possibility of nausea and vomiting after administration, patient should avoid food for at least 2 hours before administration and avoid drinking liquids at least 30 minutes prior to administration.

Other Antidepressants

Trazodone (Desyrel) blocks serotonin 2A receptor potently and blocks the serotonin reuptake pump less potently. It is indicated for depression but is often used off-label for insomnia and anxiety. Sedation is a very common side effect. Other side effects include weight gain, nausea, vomiting, constipation, dizziness, fatigue, incoordination, and tremor.

Other newly FDA-approved antidepressants target other receptor sites. For example, vilazodone (Viibryd) is a serotonin reuptake inhibitor and a partial agonist of 5-HT_{1A}; vortioxetine (Brintellix) inhibits reuptake of serotonin and norepinephrine, but is also a partial agonist to 5-HT_{1A}. These subtle differences translate into subtle clinical effects.

Tricyclic Antidepressants

The TCAs were once the primary medication used for treating depression. With the introduction of the SSRIs and other previously discussed antidepressants, the use of TCAs has significantly declined. In most cases, these medications are as effective as the other drugs, but they have more serious side effects and a higher lethal potential (see [Table 12.9](#)). The TCAs act on a variety of neurotransmitter systems, including the norepinephrine and serotonin reuptake systems.

Pharmacokinetics

The TCAs are highly bound to plasma proteins, which make the association between blood levels and therapeutic clinical effects difficult. However, some plasma ranges have been established (see [Table 12.7](#)). Most of the TCAs have active metabolites that act in as much the same manner as the parent drug. Most of these antidepressants may be given in a once-daily single dose. If the medication causes sedation, this dose should be given at bedtime.

Side Effects, Adverse Reactions, and Toxicity

Because the TCAs act on several neurotransmitters in addition to serotonin and norepinephrine, these drugs have many unwanted effects. With the TCAs, sedation, orthostatic hypotension, and anticholinergic side effects are the most common sources of discomfort for patients receiving these medications. Other side effects of the TCAs include tremors, restlessness, insomnia, nausea and vomiting, confusion, pedal edema, headache, and seizures. Blood dyscrasias may also occur, and any fever, sore throat, malaise, or rash should be reported to the prescriber. Interventions to assist in minimizing these side effects are listed in [Table 12.1](#).

The TCAs have the potential for cardiotoxicity. Symptoms include prolongation of cardiac conduction that may worsen preexisting cardiac conduction problems. The TCAs are contraindicated with second-degree atrioventricular block and should be used cautiously in patients who have other cardiac problems. Occasionally, they may precipitate heart failure, myocardial infarction, arrhythmias, and stroke.

Antidepressants that block the dopamine (D₂) receptor, such as amoxapine, have produced symptoms of NMS. Mild forms of EPS and endocrine changes, including galactorrhea and amenorrhea, may develop.

Monoamine Oxidase Inhibitors

The MAOIs, as their name indicates, inhibit MAO, an enzyme that breaks down the biogenic amine neurotransmitters serotonin, norepinephrine, and others. By inhibiting this enzyme, serotonin and norepinephrine activity is increased in the synapse. In the United States, there are three oral formulations: phenelzine (Nardil), tranylcypromine (Parnate), and isocarboxazid (Marplan) and one

available by a transdermal patch: selegiline (Emsam). These are considered MAOIs because they form strong covalent bonds to block the enzyme MAO. The inhibition of this enzyme increases with repeated administration of these medications and takes at least 2 weeks to resolve after discontinuation of use of the medication.

The major problem with the MAOIs is their interaction with tyramine-rich foods and certain medications that can result in a hypertensive crisis. All the MAOIs have dietary modification except the 6 mg/24 hours dose of selegiline. The enzyme monoamine is important in the breakdown of dietary amines (e.g., tyramine). When the enzyme is inhibited, tyramine, a precursor for dopamine, increases in the nerve cells. Tyramine has a vasopressor action that induces hypertension. If the individual ingests food that contains high levels of tyramine while taking MAOIs, severe headaches, palpitation, neck stiffness and soreness, nausea, vomiting, sweating, hypertension, stroke, and, in rare instances, death may result. Patients who are taking MAOIs are prescribed a low-tyramine diet ([Table 12.10](#)).

TABLE 12.10 EXAMPLE OF A TYRAMINE-RESTRICTED DIET

Category of Food	Food with Tyramine	Food Allowed
Nonrefrigerated food	Spoiled foods or foods not refrigerated, handled, or stored properly	Food that is handled and stored properly
Cheese	All aged and mature cheeses, especially strong, aged, or processed cheeses such as American processed cheddar, Colby, blue, brie, mozzarella, and parmesan; yogurt, sour cream	Fresh cottage cheese, cream cheese, ricotta cheese
Meat, fish, and poultry	Air-dried, aged, and fermented meats; sausages and salamis Beef or chicken liver Dried and pickled herring Pepperoni Anchovies, meat extracts, meat	Fresh meat, poultry, and fish, including fresh processed meats (e.g., lunch meats, hot dogs, breakfast sausage, and cooked sliced ham)

	tenderizers	
	Meats prepared with tenderizers,	
	improperly stored meat	
	Spoiled or improperly stored animal	
	liver	
Fruits and vegetables	Broad bean pods (Fava bean pods)	All other vegetables
Alcoholic beverages	All tap beers and other beers that have not been pasteurized; red wine, sherry, liqueurs; some alcohol-free and reduced alcohol beer	White wines may not contain tyramine.
Miscellaneous foods	Marmite concentrated yeast extract	Soy milk
	Sauerkraut	Pizzas from commercial chain restaurants prepared with cheeses low in tyramine
	Soy sauce and other soybean condiments

<https://www.fda.gov/consumers/consumer-updates/avoiding-drug-interactions>; Parke-Davis. (2007).
http://www.accessdata.fda.gov/drugsatfda_docs/label/2007/011909s038lbl.pdf

In addition to food restrictions, many prescription and nonprescription medications that stimulate the sympathetic nervous system (sympathomimetic) produce the same risk for hypertensive crisis as do foods containing tyramine. The nonprescription medication interactions involve primarily diet pills and cold remedies. Patients should be advised to check the labels of any nonprescription drugs carefully for a warning against use with antidepressants, especially the MAOIs, and then consult their prescriber before consuming these medications. In addition, symptoms of other serious drug–drug interactions may develop, such as coma, hypertension, and fever, which may occur when patients receive meperidine (Demerol) while taking an MAOI. Patients should notify other health care providers, including dentists, that they are taking an MAOI before being prescribed or given any other medication.

The MAOIs frequently produce dizziness, headache, insomnia, dry mouth, blurred vision, constipation, nausea, peripheral edema, urinary hesitancy, muscle weakness, forgetfulness, and weight gain. Older patients are especially sensitive to the side effect of orthostatic hypotension and require frequent assessment of lying and standing blood pressures. They may be at risk for falls and subsequent bone fractures and require assistance in changing position. Sexual dysfunction,

including decreased libido, impotence, and anorgasmia, also is common with MAOIs.

Antianxiety and Sedative–Hypnotic Medications

Sometimes called *anxiolytics*, antianxiety medications, such as buspirone and sedative–hypnotic medications, such as lorazepam (Ativan), come from various pharmacologic classifications, including barbiturates, benzodiazepines, nonbenzodiazepines, and nonbarbiturate sedative–hypnotic medications, such as chloral hydrate. These drugs represent some of the most widely prescribed medications today for the short-term relief of anxiety or anxiety associated with depression.

Benzodiazepines

Commonly prescribed benzodiazepines include alprazolam (Xanax), lorazepam (Ativan), diazepam (Valium), chlordiazepoxide (Librium), flurazepam (Dalmane), and triazolam (Halcion). Although benzodiazepines are known to enhance the effects of the inhibitory neurotransmitter GABA, their exact mechanisms of action are not well understood. Of the various benzodiazepines in use to relieve anxiety (and treat insomnia), oxazepam (Serax) and lorazepam (Ativan) are often preferred for patients with liver disease and for older patients because of their short half-lives.

TABLE 12.11 ANTIANXIETY AND SEDATIVE–HYPNOTIC MEDICATIONS

Generic (Trade) Drug Name	Usual Dosage Range (mg/day)	Half-Life (h)	Speed of Onset After Single Dose
Benzodiazepines			
Diazepam (Valium)	4–40	30–100	Very fast
Chlordiazepoxide (Librium)	15–100	50–100	Intermediate

Clorazepate (Tranxene)	15–60	30–200	Fast
Prazepam (Centrax)	20–60	30–200	Very slow
Lorazepam (Ativan)	2–8	10–20	Slow intermediate
Oxazepam (Serax)	30–120	3–21	Slow intermediate
Alprazolam (Xanax)	0.5–10	12–15	Intermediate
Halazepam (Paxipam)	80–160	30–200	Slow intermediate
Clonazepam (Klonopin)	1.5–20	18–50	Intermediate
Nonbenzodiazepine			
Buspirone (BuSpar)	15–30	3–11	Very slow

Pharmacokinetics

The variable rate of absorption of the benzodiazepines determines the speed of onset. [Table 12.11](#) provides relative indications of the speed of onset, from very fast to slow, for some of the commonly prescribed benzodiazepines. Whereas chlordiazepoxide (Librium) and diazepam (Valium) are slow, erratic, and sometimes incompletely absorbed when given intramuscularly, lorazepam (Ativan) is rapidly and completely absorbed when given intramuscularly.

All the benzodiazepines are highly lipid soluble and highly protein bound. They are distributed throughout the body and enter the CNS quickly. Other drugs that compete for protein-binding sites may produce drug–drug interactions. The degree to which each of these drugs is lipid soluble affects its duration of action. Most of these drugs have active metabolites, but the degree of activity of each metabolite affects duration of action and elimination half-life. Most of these drugs vary markedly in length of half-life. Oxazepam and lorazepam have no active metabolites and thus have shorter half-lives. Elimination half-lives may also be sustained for obese patients when using diazepam and chlordiazepoxide.

Side Effects, Adverse Reactions, and Toxicity

The most commonly reported side effects of benzodiazepines result from the sedative and CNS depression effects of these medications. Drowsiness, intellectual impairment, memory impairment, ataxia, and reduced motor

coordination are common adverse reactions. If prescribed for sleep, many of these medications, especially the long-acting benzodiazepines, produce significant “hangover” effects experienced on awakening. Older patients receiving repeated doses of medications such as flurazepam at bedtime may experience paradoxical confusion, agitation, and delirium, sometimes after the first dose. In addition, daytime fatigue, drowsiness, and cognitive impairments may continue while the person is awake. For most patients, the effects subside as tolerance develops; however, alcohol increases all these symptoms and potentiates the CNS depression. Individuals using these medications should be warned to be cautious when driving or performing other tasks that require mental alertness. If these tasks are part of the person’s work requirements, another medication may be chosen. Administered intravenously, benzodiazepines often cause phlebitis and thrombosis at the IV sites, which should be monitored closely and changed if redness or swelling develops.

Because tolerance develops to most of the CNS depressant effects, individuals who wish to experience the feeling of “intoxication” from these medications may be tempted to increase their own dosage. Psychological dependence is more likely to occur when using these medications for a longer period. Abrupt discontinuation of the use of benzodiazepines may result in a recurrence of the target symptoms, such as rebound insomnia or anxiety. Other withdrawal symptoms appear rapidly, including tremors, increased perspiration, palpitations, increased sensitivity to light, abdominal discomfort or pain, and elevations in systolic blood pressure. These symptoms may be more pronounced with the short-acting benzodiazepines, such as lorazepam. Gradual tapering is recommended for discontinuing use of benzodiazepines after long-term treatment. When tapering short-acting medications, the prescriber may switch the patient to a long-acting benzodiazepine before discontinuing use of the short-acting drug.

Individual reactions to the benzodiazepines appear to be associated with sensitivity to their effects. Some patients feel apathy, fatigue, tearfulness, emotional lability, irritability, and nervousness. Symptoms of depression may worsen. The psychiatric–mental health nurse should closely monitor these symptoms when individuals are receiving benzodiazepines as adjunctive treatment for anxiety that coexists with depression. Gastrointestinal disturbances, including nausea, vomiting, anorexia, dry mouth, and constipation, may develop. These medications may be taken with food to ease the gastrointestinal distress.

Older patients are particularly susceptible to incontinence, memory

disturbances, dizziness, and increased risk for falls when using benzodiazepines. Pregnant patients should be aware that these medications cross the placenta and are associated with increased risk for birth defects, such as cleft palate, mental retardation, and pyloric stenosis. Infants born addicted to benzodiazepines often exhibit flaccid muscle tone, lethargy, and difficulties sucking. All the benzodiazepines are excreted in breast milk, and breastfeeding women should avoid using these medications. Infants and children metabolize these medications more slowly; therefore, more drug accumulates in their bodies.

Toxicity develops in overdose or accumulation of the drug in the body from liver dysfunction or disease. Symptoms include worsening of the CNS depression, ataxia, confusion, delirium, agitation, hypotension, diminished reflexes, and lethargy. Rarely do the benzodiazepines cause respiratory depression or death. In overdose, these medications have a high therapeutic index and rarely result in death unless combined with another CNS depressant drug, such as alcohol.

Nonbenzodiazepines: Buspirone

Buspirone, a nonbenzodiazepine, is effective in controlling the symptoms of anxiety but has no effect on panic disorders and little effect on obsessive-compulsive disorder.

Indications and Mechanisms of Actions

Nonbenzodiazepines are effective for treating anxiety disorders without the CNS depressant effects or the potential for abuse and withdrawal syndromes. Buspirone is indicated for treating generalized anxiety disorder; therefore, its target symptoms include anxiety and related symptoms, such as difficulty concentrating, tension, insomnia, restlessness, irritability, and fatigue. Because buspirone does not add to depression symptoms, it has been tried for treating anxiety that coexists with depression. In some instances, it is thought to potentiate the antidepressant actions of other medications.

Buspirone has no effect on the benzodiazepine–GABA complex but instead appears to control anxiety by blocking the serotonin subtype of receptor, 5-HT_{1A}, at both presynaptic reuptake and postsynaptic receptor sites. It has no

sedative, muscle relaxant, or anticonvulsant effects. It also lacks potential for abuse.

Pharmacokinetics

Buspirone is rapidly absorbed but undergoes extensive first-pass metabolism. Food slows absorption but appears to reduce first-pass effects, increasing the bioavailability of the medication. Buspirone is given on a continual dosing schedule of three times a day because of its short half-life of 2 to 3 hours. Clinical action depends on reaching steady-state concentrations; taking this medication with food may facilitate this process.

Buspirone is highly protein bound but does not displace most other medications. However, it does displace digoxin and may increase digoxin levels to the point of toxicity. It is metabolized in the liver and excreted predominantly by the kidneys but also via the gastrointestinal tract. Patients with liver or kidney impairment should be given this medication with caution.

Buspirone cannot be used on a PRN basis; rather, it takes 2 to 4 weeks of continual use for symptom relief to occur. It is more effective in reducing anxiety in patients who have never taken a benzodiazepine.

Buspirone does not block the withdrawal of other benzodiazepines. Therefore, a switch to buspirone must be initiated gradually to avoid withdrawal symptoms. Nurses should closely monitor patients who are undergoing this change of medication for emergence of withdrawal symptoms from the benzodiazepines and report such symptoms to the prescriber.

Side Effects, Adverse Reactions, and Toxicity

Common side effects from buspirone include dizziness, drowsiness, nausea, excitement, and headache. Most other side effects occur at an incidence of less than 1%. There have been no reports of death from an overdose of buspirone alone. Older patients, pregnant women, and children have not been adequately studied. For now, buspirone can be assumed to cross the placenta and is present in breast milk; therefore, its use should be avoided in pregnant women, and women who are taking this medication should not breastfeed.

Antihistamines

Antihistamine, hydroxyzine (Atarax, Vistaril), is increasingly used for the treatment of anxiety as a substitute for the benzodiazepines which can lead to psychological dependence. Histamine can produce symptoms of itching or hives on the skin.

Indications and Mechanisms of Actions

Even though hydroxyzine is primarily used for itching and nausea, it is also approved for anxiety, tension, and sleep. Hydroxyzine's metabolite, *cetirizine*, blocks the H₁ histamine receptor and prevents symptoms that are caused by histamine activity on capillaries, bronchial smooth muscle, and gastrointestinal smooth muscle. It crosses the blood–brain barrier and acts on the H₁ receptors in the CNS, which results in suppression of certain subcortical regions of the brain causing sedation and anticholinergic action.

Pharmacokinetics

Hydroxyzine is rapidly absorbed and distributed in oral and IM administration and is metabolized in the liver. The effects are observed within 1 hour of administration with a peak effect in 2 hours. The elimination half-life is around 20 hours in adults (Paton & Webster, 1985).

Side Effects, Adverse Reactions, and Toxicity

The side effects include deep sleep, incoordination, sedation, calmness, and dizziness as well as hypotension, tinnitus, and headaches. Due to the anticholinergic property, constipation and dry mouth can occur. There is some evidence that hydroxyzine can prolong the QTc interval. Hydroxyzine should be avoided in older adults (Golembesky et al., 2018).

Sedative–Hypnotics

Sedatives reduce activity, nervousness, irritability, and excitability without causing sleep, but if given in large enough doses, they have a hypnotic effect. **Hypnotics** cause drowsiness and facilitate the onset and maintenance of sleep. These two classifications are usually referred to as **sedative–hypnotics**—drugs that have a calming effect or depress the CNS. These medications include (1) benzodiazepines, (2) GABA enhancers, (3) melatonergic hypnotics, (4) antihistamines, and (5) the orexin receptor antagonist (Table 12.12). The benzodiazepines have been previously discussed. The GABA enhancers modulate GABA-A receptors. They do not cause a high degree of tolerance or dependence and are easier to discontinue than the benzodiazepines. Melatonergic hypnotics are melatonin agonists, and antihistamines block histamines, causing sedation (Atkin et al., 2018). The orexin receptor antagonists block the activity of orexins, neurotransmitters involved in wakefulness and arousal. These medications are discussed thoroughly in Chapter 34.

TABLE 12.12 HYPNOTICS FOR INSOMNIA

Generic (Trade) Drug Name	Usual Dosage Range (mg/day)	Elimination Half-Life (h)	Speed of Onset After Single Dose
Benzodiazepine Hypnotics			
Flurazepam	15–30	47–100	Fast
Temazepam (Restoril)	15–30	9.5–20	Moderately fast
Triazolam (Halcion)	0.25–0.5	1.5–5	Fast
Quazepam (Doral)	0.75–15	39	Fast
Estazolam (ProSom)	1	10–24	Fast
Nonbenzodiazepine Hypnotics			
Eszopiclone (Lunesta)	2–3	6	Fast
Zaleplon (Sonata)	10	1	Fast
Zolpidem (Ambien)	5–10	2.6	Fast
Zolpidem CR (Ambien CR)	12.5	2.6	Fast

Melatonergic Hypnotics			
Melatonin	0.1–10	0.5–0.75	Fast
Ramelteon (Rozerem)	8	1–2.6	Fast
Antihistamines			
Hydroxyzine (Vistaril)	50–100	20	Fast
Doxylamine (Unisom)	25	10	Fast
Orexin Receptor Antagonist			
Suvorexant (Belsomra)	10–20 mg	12	Fast

Stimulants and Wakefulness-Promoting Agents

Amphetamines were first synthesized in the late 1800s but were not used for psychiatric disorders until the 1930s. Initially, amphetamines were prescribed for a variety of symptoms and disorders, but their high abuse potential soon became obvious.

Currently, among the medications known as stimulants are methylphenidate (Ritalin, Methylin, Metadate), *d*-amphetamine (Dexedrine), amphetamine/dextroamphetamine (Adderall), dexamethylphenidate (Focalin), lisdexamphetamine (Vyvanse), and CNS stimulants. Modafinil (Provigil) and armodafinil (Nuvigil) are wakefulness-promoting agents used for narcolepsy and other sleep disorders.

Indications and Mechanisms of Action

Medical use of these stimulants is now restricted to a few disorders, including narcolepsy, attention deficit hyperactivity disorder (ADHD), particularly in children, and obesity unresponsive to other treatments. However, stimulants are increasingly being used as an adjunctive treatment in depression and other mood disorders to address the fatigue and low energy common to these conditions.

Amphetamines indirectly stimulate the sympathetic nervous system, producing alertness, wakefulness, vasoconstriction, suppressed appetite, and hypothermia. Tolerance develops to some of these effects, such as suppression of appetite, but the CNS stimulation continues. Although the exact mechanism of action is not completely understood, stimulants cause a release of catecholamines, particularly norepinephrine and dopamine, into the synapse from the presynaptic nerve cell. They also block reuptake of these catecholamines. Methylphenidate is structurally like the amphetamines but produces a milder CNS stimulation. Psychostimulants should be used very cautiously in individuals who have a history of substance abuse.

Although the stimulant effects of these medications may seem logically indicated for narcolepsy, a disorder in which the individual frequently and abruptly falls asleep, the indications for childhood ADHD seem less obvious. The etiology and neurobiology of ADHD remain unclear, but psychostimulants produce a paradoxical calming of the increased motor activity characteristic of ADHD. Studies show that medication decreases disruptive activity during school hours, reduces noise and verbal activity, improves attention span and short-term memory, improves ability to follow directions, and decreases distractibility and impulsivity. Although these improvements have been well documented in the literature, the diagnosis of ADHD and subsequent use of psychostimulants with children remain matters of controversy (see Chapter 37).

Modafinil (Provigil) and armodafinil (Nuvigil), wake-promoting agents, are used for treating excessive sleepiness associated with narcolepsy, sleep apnea, and residual sleepiness for shift work sleep disorder. Armodafinil is longer acting than modafinil. The mechanism of action is unclear, but it is hypothesized that they increase glutamate and suppress GABA in the hypothalamus, hippocampus, and thalamus. There is no evidence of direct effects on dopamine, but there may be action on a dopamine transport. These drugs may increase the risk of Stevens–Johnson syndrome (Holfinger et al., 2018; Ogeil et al., 2019).

Pharmacokinetics

Psychostimulants are rapidly absorbed from the gastrointestinal tract and reach peak plasma levels in 1 to 3 hours. Considerable individual variations occur between the drugs in terms of their bioavailability, plasma levels, and half-lives. [Table 12.13](#) compares the primary psychostimulants used in psychiatry. Some of

these differences are age dependent because children metabolize these medications more rapidly, producing shorter elimination half-lives.

The psychostimulants appear to be unaffected by food in the stomach and should be given after meals to reduce the appetite suppressant effects when indicated. However, changes in urine pH may affect the rates of excretion. Excessive sodium bicarbonate alkalizes the urine and reduces amphetamine secretion. Increased vitamin C or citric acid intake may acidify the urine and increase its excretion. Starvation from appetite suppression may have a similar effect. All these drugs are highly lipid soluble, crossing easily into the CNS and the placenta. Psychostimulants undergo metabolic changes in the liver, where they may affect, or be affected by, other drugs. They are primarily excreted through the kidneys; therefore, renal dysfunction may interfere with excretion.

Psychostimulants are usually begun at a low dose and increased weekly, depending on the improvement of symptoms and occurrence of side effects. Initially, children with ADHD are given a morning dose so their school performance may be compared from morning to afternoon. Rebound symptoms of excitability and overtalkativeness may occur when use of the medication is withdrawn or after dose reduction. These symptoms also begin about 5 hours after the last dose of medication, which may affect the dosing regimen for some individuals. The return of symptoms in the afternoon for children with ADHD may require that a second dose be given at school. Prescribers should work with parents to implement other interventions after school and on weekends when the psychostimulants are not used. The severity of symptoms may require that the medications be continued during these times, but this dosing schedule should be determined after careful evaluation on an individual basis. Use of these medications should not be stopped abruptly, especially with higher doses, because the rebound effects may last for several days.

TABLE 12.13 PSYCHOSTIMULANT MEDICATIONS

Generic (Trade) Drug Name	Usual Dosage Range (mg/day)	Elimination Half-Life
Dextroamphetamine (Dexedrine)	5–40	Highly variable depending on urine pH
Methylphenidate (Ritalin)	10–60	2.4 h (children); 2.1 h (adults)

Amphetamine/dextroamphetamine (Adderall)	2.5 mg (3–5 y) 5 mg (6 y) 5–60 mg for narcolepsy	9–11 h
Dexmethylphenidate extended release (Focalin XR)	5–40 mg	3 h
Lisdexamphetamine (Vyvanse)	30 mg	<1 h

Modafinil (Provigil) is absorbed rapidly and reaches peak plasma concentration in 2 to 4 hours. Armodafinil reaches peak plasma concentration later and is maintained for 6 to 14 hours. Absorption of both may be delayed by 1 to 2 hours if taken with food. Modafinil is eliminated via liver metabolism with subsequent excretion of metabolites through renal excretion. They may interact with drugs that are metabolized by liver enzymes including phenytoin, diazepam, and propranolol. Concurrent use of modafinil or armodafinil and other drugs metabolized by the liver enzyme system may lead to increased circulating blood levels of the other drugs.

Side Effects, Adverse Reactions, and Toxicity

Side effects associated with psychostimulants typically arise within 2 to 3 weeks after use of the medication begins. From most to least common, these side effects include appetite suppression, insomnia, irritability, weight loss, nausea, headache, palpitations, blurred vision, dry mouth, constipation, and dizziness. Because of the effects on the sympathetic nervous system, some individuals experience blood pressure changes (both hypertension and hypotension), tachycardia, tremors, and irregular heart rates. Blood pressure and pulse should be monitored initially and after each dosage change.

Rarely, psychostimulants suppress growth and development in children. These effects are a matter of controversy, and research has produced conflicting results. Although suppression of height seems unlikely to some researchers, others have indicated that psychostimulants may have an effect on cartilage. Height and weight should be monitored several times annually for children taking these medications and compared with prior history of growth. Weight should be monitored, especially closely during the initial phases of treatment. These effects also may be minimized by drug “holidays,” such as during school vacations.

Rarely, individuals may experience mild dysphoria, social withdrawal, or mild-to-moderate depression. These symptoms are more common at higher doses and may require discontinuation of use of medication. Abnormal movements and motor tics may also increase in individuals who have a history of Tourette syndrome. Psychostimulants should be avoided by patients with Tourette symptoms or with a positive family history of the disorder. In addition, dextroamphetamine has been associated with an increased risk for congenital abnormalities. Because there is no compelling reason for a pregnant woman to continue to take these medications, patients should be informed and should advise their prescriber immediately if they plan to become pregnant or if pregnancy is a possibility.

Death is rare from overdose or toxicity of the psychostimulants, but a 10-day supply may be lethal, especially in children. Symptoms of overdose include agitation, chest pain, hallucinations, paranoia, confusion, and dysphoria. Seizures may develop, along with fever, tremor, hypertension or hypotension, aggression, headache, palpitations, rashes, difficulty breathing, leg pain, and abdominal pain. Toxic doses of dextroamphetamine are above 20 mg, with potential death resulting from a 400-mg dose. Parents should be warned regarding the potential lethality of these medications and take preventive measures by keeping the medication in a safe place.

Side effects associated with modafinil and armodafinil include nausea, nervousness, headache, dizziness, and trouble sleeping. If the effects continue or are bothersome, patients should consult the prescriber. Modafinil and armodafinil are generally well tolerated with few clinically significant side effects. It is potentially habit forming and must be used with great caution in individuals with a history of substance abuse or dependence (Cephalon, 2017).

INTEGRATIVE AND COMPLEMENTARY HEALTH CARE

Herbal Therapies

Integrative health care expands and incorporates treatment modalities outside the norm of Western medicine. Herbal therapies are often used in addition to or in place of antidepressants and anxiety medication (Shah et al., 2017). An in-

depth discussion of herbal therapies is outside the scope of this text, and readers are encouraged to seek additional resources from the National Center for Complementary and Integrative Health within the National Institutes of Health.

This chapter discusses dietary supplements and herbal therapies commonly used by persons receiving mental health care. These are exempt from the FDA's efficacy and safety standards because they are considered food. Lack of regulation does not mean that these supplements are ineffective or unsafe. These substances can be effective but can also have adverse reactions and interact with prescribed medications. Nurses need to understand these potential interactions and assess their patients for the impact of these substances.

St. John's wort (SJW), derived from *Hypericum perforatum* L., is used for depression, pain, anxiety, insomnia, and premenstrual syndrome. SJW is believed to modulate serotonin, dopamine, and norepinephrine. The risk of developing serotonin syndrome is increased when taken with other serotonergic drugs. It has the potential to interact with other medications (i.e., birth control pills, digoxin) and should not be taken with prescribed antidepressants (National Center for Complementary & Integrative Health, [NCCIH], 2020; Nicolussi et al., 2020).

Kava, derived from the *Piper methysticum* plant, is used for anxiety reduction. Kava interacts with dopaminergic transmission, inhibits the MAO-B enzyme system, and modulates the GABA receptor. It may also inhibit uptake of noradrenaline. Kava is widely used by Pacific Islanders as a social and ceremonial tranquilizing drink. In 2002, the FDA issued warnings about the risk of severe liver injury associated with kava. Several countries have restricted its use. Thrombocytopenia, leukopenia, and hearing impairment have been reported with the use of kava (National Center for Complementary and Integrative Health., 2020; Raziq, 2020).

Valerian (*Valeriana officinalis*), a member of the Valerianaceae family, is a perennial plant native to Europe and Asia and naturalized to North America. Valerian is a common ingredient in products promoted for insomnia and nervousness. The evidence of its effectiveness is inconclusive. The mechanism of action is unclear but appears to be relatively safe. There are some reports that suggest hepatotoxicity in humans (NCCIH, 2018; Hoban et al., 2019).

Vitamin, Mineral, and Other Dietary Supplements

The neurotransmitters necessary for normal healthy functioning are produced from chemical building blocks taken in with the foods we eat. Many nutritional deficiencies may produce symptoms of psychiatric disorders. Fatigue, apathy, and depression are caused by deficiencies in iron, folic acid, pantothenic acid, magnesium, vitamin C, or biotin. Logically, treating these deficiencies with dietary supplements should improve the psychiatric symptoms. The question becomes, Can nutritional supplements improve psychiatric symptoms that are not the result of such deficiencies?

Tryptophan, the dietary precursor for serotonin, is involved in several physiological processes including neuronal function, immunity, and gut homeostasis. Tryptophan is metabolized into biologically active compounds such as serotonin, melatonin, and niacin and has been most extensively investigated as it relates to low serotonin levels and increased aggression. It is involved in diseases in the CNS, malignancy, inflammatory bowel, and cardiovascular disease. Individuals who have low tryptophan levels are prone to have lower levels of serotonin in the brain, resulting in depressed mood and aggressive behavior (Comai et al., 2020).

Dietary supplements such as melatonin and lecithin target CNS functioning. Melatonin, a naturally occurring hormone secreted from the pineal gland, is used for treatment of insomnia and prevention of “jet lag” in air travelers. Lecithin, a precursor to acetylcholine, is used to improve memory and treat dementia. The extent to which the level of acetylcholine is raised by ingestion of lecithin is unknown (Tayebati, 2018).

Medications may also influence the development of nutritional deficiencies that may worsen psychiatric symptoms. For example, drugs with strong anticholinergic activity often produce impaired or enhanced gastric motility, which may lead to generalized malabsorption of vitamins and minerals. In addition, many vitamin and mineral supplements have toxicities of their own when given in excess. For example, daily ingestion of more than 100 mg of pyridoxine (vitamin B₆) can produce neurotoxic symptoms, photosensitivity, and ataxia. More research is needed to identify the underlying mechanisms and relationships of dietary supplements and dietary precursors of the bioamines to mood and behavior and psychopharmacologic medications. For now, it is important for the psychiatric–mental health nurse to recognize that these issues may be potential factors in improvement of the patient’s mental status and target symptoms.

OTHER BIOLOGIC TREATMENTS

Although the primary biologic interventions remain pharmacologic, other somatic treatments have gained acceptance, remain under investigation, or show promise for the future. These include neurosurgery, ECT, phototherapy, and (most recently) rTMS and VNS. The use of neurosurgery is very limited and outside the scope of this text.

Electroconvulsive Therapy

For hundreds of years, seizures have been known to produce improvement in some psychiatric symptoms. Camphor-induced seizures were used in the 16th century to reduce psychosis and mania. With time, other substances, such as inhalants, were tried, but most were difficult to control or produced adverse reactions, sometimes even fatalities. ECT was formally introduced in Italy in 1938. It is one of the oldest medical treatments available and remains safely in use today. It is one of the most effective treatments for severe depression but has been used for other disorders, including mania and schizophrenia, when other treatments have failed.

With ECT, a brief electrical current is passed through the brain to produce generalized seizures lasting 25 to 150 seconds. The patient does not feel the stimulus or recall the procedure. A short-acting anesthetic and a muscle relaxant are given before induction of the current. A brief pulse stimulus, administered unilaterally on the nondominant side of the head, is associated with less confusion after ECT. However, some individuals require bilateral treatment for effective resolution of depressive symptoms. Induction of a seizure is necessary to produce positive treatment outcomes. Because individual seizure thresholds vary, the electrical impulse and treatment method also may vary. In general, the lowest possible electrical stimulus necessary to produce seizure activity is used. Blood pressure and the ECG are monitored during the procedure. This procedure is repeated two or three times a week, usually for a total of 6 to 12 treatments. Because there is no difference in treatment efficacy and a twice-weekly regimen produces less accumulative memory loss, this treatment course is often chosen. After symptoms have improved, antidepressant medication may be used to prevent relapse. Some patients who cannot take or do not experience response to

antidepressant treatment may continue to have ECT treatment. Usually, once-weekly treatments are gradually decreased in frequency to once monthly. The number and frequency vary depending on the individual's response.

Although ECT produces rapid improvement in depressive symptoms, its exact mechanism of antidepressant action remains unclear. It is known to downregulate β -adrenergic receptors in much the same way as antidepressant medications. However, unlike antidepressant therapy, ECT produces an upregulation in serotonin, especially 5-HT₂. ECT also has several other actions on neurochemistry, including increased influx of calcium and effects on second messenger systems.

Brief episodes of hypotension or hypertension, bradycardia or tachycardia, and minor arrhythmias are among the adverse reactions that may occur during and immediately after the procedure but usually resolve quickly. Common aftereffects from ECT include headache, nausea, and muscle pain. Memory loss is the most troublesome long-term effect of ECT. Many patients do not experience amnesia, but others report some memory loss for months or even years. Evidence is conflicting on the effects of ECT on the formation of memories after the treatments and on learning, but most patients experience no noticeable change. Memory loss occurring as part of the symptoms of untreated depression presents a confounding factor in determining the exact nature of the memory deficits from ECT. It is important to remember that patient surveys are positive, with most individuals reporting that they were helped by ECT and would have it again (Brown et al., 2018).

ECT is contraindicated in patients with increased intracranial pressure. Risk also increases in patients with recent myocardial infarction, recent cerebrovascular accident, retinal detachment, or pheochromocytoma (a tumor on the adrenal cortex) and in patients at high risk for complications from anesthesia. Although ECT should be considered cautiously because of its specific side effects, added risks of general anesthesia, possible contraindications, and substantial social stigma, it is a safe and effective treatment.

Psychiatric-mental health nurses are involved in many aspects of care for individuals undergoing ECT. Informed consent is required, and all treating professionals have a responsibility to ensure that the patient's and family's questions are answered completely. Available treatment options, risks, and consequences must be fully discussed. Sometimes, memory difficulties associated with severe depression make it difficult for patients to retain information or ask questions. Nurses should be prepared to restate or explain the

procedure as often as necessary. Whenever possible, the individual's family or other support systems should be educated and involved in the consent process. Educational videos are available, but they should not replace direct discussions. Language should be in terms the patient and family members can understand. Other nursing interventions involve preparation of the patient before treatment, monitoring immediately after treatment, and follow-up. Many of these considerations are listed in [Box 12.5](#).

BOX 12.5

Interventions for the Patient Receiving Electroconvulsive Therapy

- Discuss treatment alternatives, procedures, risks, and benefits with patient and family. Make sure that informed consent for ECT has been given in writing.
- Provide initial and ongoing patient and family education.
- Assist and monitor the patient who must take NPO after midnight, the evening before the procedure.
- Make sure that the patient wears loose, comfortable, nonrestrictive clothing to the procedure.
- If the procedure is performed on an outpatient basis, ensure that the patient has someone to accompany them home and stay with them after the procedure.
- Ensure that pretreatment laboratory tests are complete, including a CBC, serum electrolytes, urinalysis, ECG, chest radiography, and physical examination.
- Teach the patient to create memory helps, such as lists and notepads, before the ECT.
- Explain that no foreign or loose objects can be in the patient's mouth during the procedure. Dentures will be removed, and a bite block may be inserted.
- Insert an IV line and provide oxygen by nasal cannula (usually 100% oxygen at 5 L/min).
- Obtain emergency equipment and be sure it is available and ready if needed.
- Monitor vital signs frequently immediately after the procedure, as in every postanesthesia recovery period.
- When the patient is fully conscious and vital signs are stable, assist them to get up slowly, sitting for some time before standing.
- Monitor confusion closely; the patient may need reorientation to the bathroom and other areas.
- Maintain close supervision for at least 12 hours and continue observation for 48 hours after treatment. Advise family members to observe how the patient manages at home, provide assistance as needed, and report any problems.
- Assist the patient to keep or schedule follow-up appointments.

CBC, complete blood count; ECG, electrocardiogram; ECT, electroconvulsive therapy; IV, intravenous; NPO, nothing by mouth.

Light Therapy (Phototherapy)

Human circadian rhythms are set by time clues (*Zeitgebers*) inside and outside

the body. One of the most powerful regulators of these body patterns is the cycle of daylight and darkness.

Research findings indicate that some individuals with certain types of depression may experience disturbance in these normal body patterns or of circadian rhythms, particularly those who experience a seasonal variation in their depression. These individuals are more depressed during the winter months, when there is less light; they improve spontaneously in the spring (see Chapter 26). These individuals usually have symptoms that are somewhat different from classic depression, including fatigue, increased need to sleep, increased appetite and weight gain, irritability, and carbohydrate craving. Sometimes, the symptoms appear in the summer, and some individuals have only subtle changes without developing the full pattern. Administering artificial light to these patients during winter months has reduced these depressive symptoms.

Light therapy, sometimes called **phototherapy**, involves exposing the patient to an artificial light source during winter months to relieve seasonal depression. Artificial light is believed to trigger a shift in the patient's circadian rhythm to an earlier time. The light source must be very bright, full-spectrum light, usually 2500 lux, which is about 200 times brighter than normal indoor lighting. Harmful ultraviolet light is filtered out. Exposure to this light source has produced improvement and relief of depressive symptoms for significant numbers of seasonally and nonseasonally depressed individuals. Research remains ongoing (Geoffroy et al., 2019).

Studies have shown that morning phototherapy produces a better response than either evening or morning and evening timing of the phototherapy session. Light banks with full-spectrum light may be put together by the individual or obtained from various companies now producing these light sources. Light visors (visors containing small, full-spectrum light bulbs that shine on the eyelids) have also been developed. The patient is instructed to sit in front of the lights at about 3 ft, engaging in a variety of other activities, but glancing directly into the light every few minutes. This should be done immediately on arising and is most effective before 8 *am*. The duration of administration may begin with as little as 30 minutes and increase to 2 to 5 hours. One to 2 hours is usually sufficient, and the antidepressant response begins in 1 to 4 days, with the full effect usually complete after 2 weeks. Full antidepressant effect is usually maintained with daily sessions of 30 minutes (Geoffroy et al., 2019).

Side effects of phototherapy are rare, but eye strain, headache, and insomnia are possible. An ophthalmologist should be consulted if the patient has a

preexisting eye disorder. In rare instances, phototherapy has been reported to produce an episode of mania. Irritability is a more common complaint. Follow-up visits with the prescriber or therapist are needed to help manage side effects and assess positive results. Phototherapy should be implemented only by a provider knowledgeable in its use.

Transcranial Magnetic Stimulation

Transcranial magnetic stimulation (TMS) was introduced in 1985 as a noninvasive, painless method to stimulate the cerebral cortex. There are two types of TMS. The repetitive transcranial magnetic stimulation (rTMS) and the deep transcranial magnetic stimulation (dTMS). Both types are effective. Undergirding this procedure is the hypothesis that a time-varying magnetic field will induce an electrical field, which, in brain tissue, activates inhibitory and excitatory neurons, thereby modulating neuroplasticity in the brain. The low-frequency electrical stimulation from rTMS triggers lasting anticonvulsant effects in rats, and the therapeutic benefits of rTMS in humans are thought to be related to an action like that produced by anticonvulsant medication. The rTMS has been used for both clinical and research purposes. The rTMS stimulation of the brain's prefrontal cortex may help some depressed patients in much the same way as ECT but without its side effects (Trevizol & Blumberger, 2019). Thus, it has been proposed as an alternative to ECT in managing symptoms of depression. The rTMS treatment is administered daily for at least 1 week, much like ECT, except that subjects remain awake. Although proven effective for depression, rTMS does have some side effects, including mild headaches.

Vagus Nerve Stimulation

VNS sends electrical impulses to the brain to improve depression. The vagus nerve has traditionally been considered a parasympathetic efferent nerve that was responsible only for regulating autonomic functions, such as heart rate and gastric tone. However, the vagus nerve (cranial X) also carries sensory information to the brain from the head, neck, thorax, and abdomen, and research has identified that the vagus nerve has extensive projections of its sensory afferent connections to many brain areas. Although the basic mechanism of

action of VNS is unknown, incoming sensory, or afferent, connections of the left vagus nerve directly project into many of the very same brain regions implicated in neuropsychiatric disorders. These help us to understand how VNS is helpful in treating psychiatric disorders. VNS connections change levels of several neurotransmitters implicated in the development of major depression, including serotonin, norepinephrine, GABA, and glutamate, in the same way that antidepressant medications produce their therapeutic effect (Redgrave et al., 2018).

Approved by the FDA for the adjunctive treatment of severe depression for adults who are unresponsive to four or more adequate antidepressant treatments, VNS is a permanent implant. VNS is not a cure for depression, and patients must be seen regularly for assessment of mood states and suicidality.

THE ISSUE OF ADHERENCE

Medications and other biologic treatments work only if they are used. On the surface, **adherence**, or **compliance** to a therapeutic routine, seems amazingly simple. However, following therapeutic regimens, self-administering medications as prescribed, and keeping appointments are amazingly complex activities that often prevent successful treatment. In recovery-oriented practice, the patient makes the decision to take medications. It is important that the patient does not feel coerced into taking the medication. The nurse's role is to support the patient's decision-making process and provide honest, evidence-based advice.

Adherence exists on a continuum and can be conceived of as full, partial, or nil. Partial adherence, whereby a patient either attempts to take medications but misses doses or takes more than prescribed, is by far the most common. Recent estimates indicate that on the average, 50% or more of the individuals with schizophrenia taking antipsychotic medications stop taking the medications or do not take them as prescribed. It should be remembered that problems with adherence are an issue with many chronic health states, including diabetes and arthritis, not just psychiatric disorders. [Box 12.6](#) lists some of the common reasons for nonadherence. Psychiatric-mental health nurses should be aware that several factors contribute to the decision to discontinue medications.

The most often cited reasons for not taking medications as prescribed are the side effects. Medication side effects may interfere with work performance or

other important aspects of the individual's life. For example, a construction worker cannot afford to be drowsy and sedated while operating a crane at a construction site, and a woman in an intimate relationship may find anorgasmia intolerable. Even though symptom improvement may be observed by health care professionals, they may not be noticed by the patient. Nurses need to be sensitive to the patient's ability to tolerate side effects and to the impact that side effects have on the patient's life. Medication choice, dosing schedules, and prompt treatment of side effects may be crucial factors in helping patients continue with their treatment.

Cognitive deficits associated with some psychiatric disorders may make it difficult for the individual to self-monitor, develop insight, make choices, remember to fill prescriptions, or keep appointments. Forgetfulness, cost, and confusion regarding dosage or timing may also contribute to noncompliance. New advances in medication formulation are designed to address some of these issues. For example, long-acting injections are designed to reduce or eliminate the need to remember an oral medication regime. Recently, the FDA approved a tablet formulation of an antipsychotic aripiprazole embedded with a digital adherence-assessment device. The system consists of an ingestible sensor, a wearable sensor, and software applications that confirm adherence. More research is needed to confirm the practicality of using the device and its effectiveness in improving treatment adherence (Papola et al., 2018).

BOX 12.6

Common Reasons for Not Taking Medications as Prescribed

- Uncomfortable side effects and those that interfere with quality of life, such as work performance or intimate relationships
- Lack of awareness or denial of illness
- Stigma
- Feeling better
- Confusion about dosage or timing
- Difficulties in access to treatment
- Substance abuse

Family members may have similar difficulties that influence the individual not to take the medication. They may misunderstand or deny the illness, thinking, for example, “My wife's better, so she doesn't need that medicine anymore.”

Family members may be distressed when observable side effects occur. Adherence concerns must not be dismissed as the patient's or family's problem. Psychiatric nurses should actively address this issue. A positive therapeutic relationship between the nurse and patient and family must provide a strong sense of trust that side effects and other difficulties in treatment will be addressed and minimized. When individuals report experiencing distressing side effects, the nurse should immediately respond with assessment and interventions to reduce these effects. It is important to assess compliance often, asking questions in a nonthreatening, nonjudgmental manner. It also may be helpful to seek information from others who are involved with the patient.

Adherence can be improved by psychoeducation. This approach is most helpful if it addresses the individual's specific symptoms and concerns. For example, if the patient is having difficulty with understanding the purpose of the medication, it may be helpful to link taking it to reduction of specific unwanted symptoms or improved functioning, such as continuing to work. Family members should also be included in these discussions.

Other factors that interfere with adherence should also be assessed and plans developed to minimize their effect. For example, an individual who is being considered for clozapine therapy may have missed several appointments in the past. On assessment, the nurse may discover that it takes the individual 2 hours on three different buses each way to reach the clinic. The nurse can then assist with arranging for a home health nurse to visit the patient's apartment, draw blood samples for analysis, and assess side effects, thus decreasing the number of trips the patient must make to the clinic.

SUMMARY OF KEY POINTS

- Target symptoms and side effects of medications should be clearly identified. The FDA approves the use of medications for specific disorders and symptoms.
- Psychiatric medications primarily act on CNS receptors, ion channels, enzymes, and carrier proteins. Agonists mimic the action of a specific neurotransmitter; antagonists block the response.
- A drug's ability to interact with a given receptor type depends on three

qualities: selectivity—the ability to interact with specific receptors while not affecting other tissues and organs; affinity—the degree of strength of the bond between drug and receptor; and intrinsic activity—the ability to produce a certain biologic response.

- Pharmacokinetics refers to how the human body processes the drug, including absorption, distribution, metabolism, and excretion. Bioavailability describes the amount of the drug that reaches circulation throughout the body. The wide variations in the way each individual processes any medication often are related to physiologic differences caused by age, genetic makeup, other disease processes, and chemical interactions.
- Antipsychotic medications are drugs used in treating patients with psychotic disorders, such as schizophrenia. They act primarily by blocking dopamine or serotonin postsynaptically. In addition, they have several actions on other neurotransmitters. Older typical antipsychotic drugs work on positive symptoms and are inexpensive but produce more side effects than the newer atypical antipsychotic drugs which work on positive and negative symptoms.
- Medication-related movement disorders are a particularly serious group of side effects that principally occur with the typical antipsychotic medications and that may be acute syndromes, such as dystonia, pseudoparkinsonism, and akathisia, or chronic syndromes, such as tardive dyskinesia.
- The mood stabilizers, or antimanic medications, are drugs used to control wide variations in mood related to mania, but these agents may also be used to treat patients with other disorders. Lithium and the anticonvulsants are chemically unrelated and act in different ways to stabilize mood.
- Antidepressant medications are drugs used primarily for treating symptoms of depression. They act by blocking reuptake of one or more of the bioamines, especially serotonin and norepinephrine. These medications vary considerably in their structure and action. Newer antidepressants, such as the SSRIs, have fewer side effects and are less lethal in overdose than the older TCAs.
- Antianxiety medications also include several subgroups of medications, but

the benzodiazepines and nonbenzodiazepines are those principally used in psychiatry. The benzodiazepines act by enhancing the effects of GABA, and the nonbenzodiazepine buspirone acts on serotonin. Benzodiazepines can be used on a PRN basis, but buspirone, the one available nonbenzodiazepine, must be taken regularly.

- Psychostimulants enhance neurotransmitter activity, acting at several sites in the nerves. These medications are most often used for treating symptoms related to ADHD and narcolepsy.
- ECT uses the application of an electrical pulsation to induce seizures in the brain. These seizures produce several effects on neurotransmission that result in the rapid relief of depressive symptoms.
- rTMS and VNS are two emerging somatic treatments for psychiatric disorders. They are both means to directly affect brain function through stimulation of the nerves that are direct extensions of the brain.
- Phototherapy involves the application of full-spectrum light in the morning hours, which appears to reset circadian rhythm delays related to seasonal affective disorder and other forms of depression. Nutritional therapies are in various stages of investigation.
- Adherence refers to the ability of an individual to self-administer medications as prescribed and to follow other instructions related to medication treatment. It can be full, partial, or nil. Nonadherence is related to factors such as medication side effects, stigma, and family influences. Nurses play a key role in educating patients and helping them to improve adherence.

Unfolding Patient Stories: David Carter

Part 1

David Carter is a 28-year-old male with schizophrenia. He became violent and was brought to the emergency room with paranoid delusions and

auditory hallucinations. During admission, he was alternately agitated and withdrawn. Medications ordered include: olanzapine 10 mg orally daily, venlafaxine 75 mg XR orally daily, Lorazepam 2 mg orally every 8 hours as needed for agitation, and haloperidol 5 mg orally every 8 hours as needed for agitation. Describe the classification, action, dosing, and side effects for each medication? What monitoring should the nurse consider for each medication and when administering the as-needed medications? What client teaching should the nurse provide when administering the medications while considering his alternate states of agitation and withdrawal?

CRITICAL THINKING CHALLENGES

1. Discuss how you would go about identifying the target symptoms for a specific patient for the following medications: antipsychotic, antidepressant, and anti-anxiety drugs.
2. Track the approval process from identification of a potential substance to marketing a medication. Compare at least three psychiatric medications that are in phase III trials (hint: www.FDA.gov).
3. Obtain the PIs for the three atypical antipsychotics, two SSRIs, and one SNRI. Compare their boxed warnings, pharmacodynamics, pharmacokinetics, indications, side effects, and dosages.
4. Compare the oral and IM dose of lorazepam. Why are these doses similar?
5. Mr. J. has schizophrenia and was just prescribed an antipsychotic. His family wants to know the risk–benefits of the medication. How would you answer?
6. Identify the CYP450 enzyme that metabolizes the following medications: risperidone, olanzapine, quetiapine, clozapine, fluoxetine, venlafaxine, trazodone, nefazodone, and bupropion.
7. Find the four medications or substances that induce or inhibit the following CYP450 enzymes: 2D6, 2C19, 3A4, and 1A2.
8. Obtain the PI for clozapine, risperidone, quetiapine, and Risperdal Consta. Compare the half-lives of each drug. Discuss the relationship of the drug's half-life to the dosing schedule. When is steady state reached in each of these medications?
9. Explain the health problems associated with anticholinergic side effects of the antipsychotic medications.
10. Compare the type of movements that characterize tardive dyskinesia with

those that characterize akathisia and dystonia and explore which one is easier for a patient to experience.

1. One patient is prescribed the MAOI Emsam, 6 mg/day, and another is taking another MAOI, Nardil, 15 mg/day. Are the dietary restrictions different?
2. A patient who is taking an MAOI asks you to explain what will happen if she eats pizza. Prepare a short teaching intervention beginning with the action of the medication and its consequences.
3. Explain how your nursing care would be different for a male patient taking lithium carbonate than for a female patient.
4. Patient A is taking valproic acid (Depakote) for mood stabilization, and patient B is taking lamotrigine (Lamictal). After comparing notes with each other, they ask you why patient A must have drug blood levels and patient B does not. How are these two drugs alike? How are they different?
5. Two patients are getting their blood drawn. One patient is getting lithium and the other clozapine. What laboratory tests are being ordered?
6. A patient who is depressed has been started on sertraline. During the assessment, she tells you that she is also taking SJW, lecithin, and a multiple vitamin. What is your next step?
7. Compare different approaches that you might use with a patient with schizophrenia who has decided to stop taking their medication because of intolerance to side effects.

Cognitive Interventions in Psychiatric Nursing

Mary Ann Boyd and Jeanne Clement-Alvarez

KEYCONCEPTS

- cognitive behavioral therapy
- rational emotive behavior therapy
- solution-focused brief therapy

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Discuss the history of cognitively based therapeutic interventions.
2. Identify the concepts underlying cognitive interventions.
3. Compare and contrast three forms of cognitively based therapies.
4. Apply cognitive interventions in a clinical setting.
5. Describe the contexts in which psychiatric nurses use cognitive interventions.

KEY TERMS

- ABCDE
- Activating event
- Belief system
- Cognition
- Cognitive interventions
- Cognitive distortions
- Cognitive triad
- Compliments
- Dysfunctional consequences
- Exception questions
- Functional consequences
- Miracle questions
- Relationship questions
- Scaling questions
- Schema

INTRODUCTION

Psychiatric nurses use evidence-based cognitive interventions in a variety of practice settings (inpatient and outpatient). The knowledge and skills inherent in cognitively based interventions have been extensively studied and their effectiveness has been demonstrated for a variety of psychiatric disorders, especially depression (see [Chapter 23](#)) and anxiety disorders (see [Chapter 25](#)). Cognitive interventions are based on the concept of cognition.

Cognition can be defined as an internal process of perception, memory, and

judgment through which an understanding of self and the world is developed. **Cognitive interventions** aim to change or reframe an individual's automatic thought patterns that have developed over time and which interfere with the individual's ability to function optimally. The skills and techniques that were developed on the basis of cognitive theory result in a new view of self and the environment.

Cognitive interventions had their beginnings in the long-term inpatient environment, but today they are a mainstay of psychiatric care in all settings and are used by all disciplines and at all levels of practice. Evidence from several studies, and as reinforced by meta-analysis of groups in the past decade, supports the use of cognitive therapies with a wide variety of psychological and psychiatric conditions, and it has been shown to be effective with diverse individuals in diverse settings (Olthuis, 2016; Shepardson et al., 2020). Cognitive therapies are incorporating additional therapeutic modalities such as mindfulness and targeting for persons with anxiety and depressive disorders (Cladder-Micus et al., 2018). The current chapter explains the theoretical perspectives and application of cognitive interventions.

DEVELOPMENT OF COGNITIVE THERAPIES

Cognitive therapy was first developed and implemented in the 1950s by Albert Ellis (1913–2007), a psychologist, who was uncomfortable with the nondirective Freudian and neo-Freudian approaches. According to Ellis, cognition, emotions, and behavior are integrated and holistic. From the 1950s until his death, Ellis continued to develop and refine his theory and therapeutic approach into what he calls rational emotive behavior therapy (REBT; Ellis et al., 2008).

Beginning in the 1960s, other cognitively based theories and therapeutic approaches were developed, the most prominent being cognitive behavioral therapy (CBT) by Aaron Beck (see [Chapter 7](#)) (Beck, 2008). Steven de Shazer (1940–2005) and Insoo Kim Berg (1934–1997) developed solution-focused brief therapy (SFBT), an approach that is useful with persons who have diagnoses such as depression, obsessive–compulsive disorder, schizophrenia, and other psychiatric disorders (Franklin et al., 2017). These models will be discussed in the current chapter.

COGNITIVE THERAPY MODELS

Cognitive approaches are congruent with the standards of practice and are particularly effective in challenging care environments. Brief cognitive therapies offer approaches that can be applied within the therapeutic patient–nurse relationship and the nursing process. Patients undergoing cognitively based psychotherapy are frequently treated by an interdisciplinary team that supports this approach.

Cognitive Behavioral Therapy

KEYCONCEPT Cognitive behavioral therapy (CBT) is a highly structured psychotherapeutic method used to alter distorted beliefs and problem behaviors by identifying and replacing negative inaccurate thoughts and changing the rewards for behaviors.

In CBT, the relationship between thoughts, feelings, and behavior is examined and identified. CBT operates on the following assumptions:

- People are disturbed not by an event but by the perception of that event.
- Whenever and however a belief develops, the individual believes it.
- Work and practice can modify beliefs that create difficulties in living.

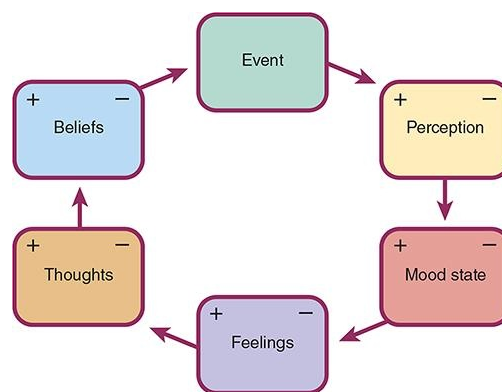

Figure 13.1 Model of perception, thoughts, and mood states: the cycle of cognition.

Figure 13.1 depicts the interaction of individual experiences, perception of these experiences, and the unique thoughts attached to these experiences that influence the development of beliefs (functional or dysfunctional). The person develops an

explanation of their relationship to their environment and to other people from these beliefs. Dysfunctional thinking develops from a variety of human experiences and can become the predominant way the world is viewed. To quote from Shakespeare's *Hamlet*, "For there is nothing either good or bad but thinking makes it so."

Thoughts have a powerful effect on emotion and behavior. By changing dysfunctional thinking, a person can alter their emotional reaction to a situation and reinterpret the meaning of an event. That is, by identifying, analyzing, and changing thoughts and behaviors that are counterproductive, feelings such as helplessness, anxiety, and depression can be reduced. The goal of CBT is to restructure how a person perceives events in their life to facilitate behavioral and emotional change.

Cognitive Processes

Three cognitive processes are involved in the development of common mental disorders such as depression. These processes include the cognitive triad, cognitive distortions, and schema.

The **cognitive triad** includes thoughts about oneself, the world, and the future. Accumulation of thoughts about oneself is reflected in spoken and unspoken beliefs and moods that grow out of these beliefs. Emotions and behavior reflect the strength of the accumulated beliefs. Dysfunctional thoughts about the self are usually overly negative or overly positive whereas functional thoughts more closely reflect the reality of the perceived situation. For example, one student has the belief that learning is very difficult for them and that they will fail the examination no matter how hard they study. He does not study for the examination because he believes that he will fail anyway. A second student believes that she is very bright, understands the material, and does not need to study. She attends a concert the night before the test. A third student believes that he has a grasp of the material to be covered on the test but ensures this by studying notes and the text before the examination. The first two students fail the examination. Failure for the first student reinforces the dysfunctional belief that no matter what, he will fail. The second student argues that the test was unfair, which also reinforces her dysfunctional belief that she is bright and understands the material. The third student earned a good grade. His functional thoughts and behaviors are also reinforced.

Students one and two mentioned earlier both hold distinctive views that are not supported by empirical evidence but are generated automatically in response to a given situation. These automatic thoughts are called **cognitive distortions** and are generated by organizing distorted information and/or inaccurate interpretation of a situation. Cognitive distortions or “twisted thinking” occurs in a variety of ways such as *overgeneralization* (asserting that something general is always true about an event, situation or group of people), *personalizing* (applying a general statement to oneself), *catastrophizing* (viewing or talking about an event as worse than it actually was), and *selective abstraction* (selectively abstracting negative information from stressful events) (see [Box 13.1](#)) (Del Pozo et al., 2018).

BOX 13.1 **CLINICAL VIGNETTE**

Cognitive Distortions

Amy has been working on a group project with her classmates in a psychiatric nursing course. Part of the process for the group project is to provide anonymous peer evaluation of the work of each of the six group members. Amy received a score of 10/10 from four of the members, a 7/10 from another, and 5/10 from the sixth. Amy thinks, “I guess I didn’t do a good job on this project. I never do anything right. My classmates look down on me.”

What Do You Think?

- What cognitive distortions does Amy exhibit?

Schemas are the individual’s life rules that act as a sieve or filter. They allow only information compatible with the internal picture of self and the world to be brought to the person’s awareness. Schemas develop in early childhood and become relatively fixed by middle childhood. Schemas are an accumulation of learning and experience from the individual’s genetic makeup, family and school environments, peer relationships, and society as a whole. Ethnicity, culture, gender, and religious affiliation influence schema development, as well as the age of the individual at the time a given event occurs, the influence of the persons or circumstances involved on how that event is perceived, and the relative strength of that influence. In the example, student number one believes

that he is not intelligent. This belief could have initiated in early childhood if the student was constantly unfavorably compared with an older sibling. This schema increases vulnerability in a host of interpersonal situations, particularly those that relate to scholarly endeavors. Student number two was overly praised by parents and other relatives and developed a schema of being more accomplished than most.

Implementing Cognitive Behavioral Therapy

The use of CBT is based on a collaborative therapeutic relationship in which a mutual trust develops through promoting patients' strengths and control over their own lives. CBT assumes that individuals have the innate ability to solve their own problems; thus, the overarching treatment goal is for the patient to be able to engage in self-care, independent of professional assistance.

In CBT, goals are developed in partnership and supply a forward-looking focus for what "can be" in the future as opposed to "what happened" in the past. The present serves as a platform from which current perceptions of earlier events can be reexamined. Movement toward goals is facilitated by strategies designed to engage the patient in the service of their own mental health. Strategies emerge when nurse and patient develop a working conceptualization of the issue or problem as the patient sees it. The nurse educates the patient about the therapeutic approach. An agenda is mutually established for each therapeutic interaction. Techniques that focus on both cognition and behavior are used to promote patient growth.

Engagement and Assessment

The first step in CBT is engagement and assessment. In this phase, the therapist establishes rapport with the patient and develops the theme that problems are manageable. The patient's definition of the problem that brought them into treatment is explored through a series of open-ended questions. A problem list is developed and reframed into manageable goals that are prioritized. The prioritized list forms the agenda for the treatment plan and structures the content of each individual session. A contract is developed for a number of sessions (frequently 10–12). The therapist seeks information about the patient's strengths and successes on which to base reexamination and reframing of negative beliefs

and to design interventions. During all sessions, the therapist summarizes issues identified and develops homework assignments that enhance and expand the work done during the sessions.

Intervention Framework

Specific interventions used with CBT, in addition to the interaction that takes place in the therapy sessions, revolve around carefully crafted homework assignments that the patient works on in the time between sessions. Subsequently, sessions may be scheduled regularly once or twice a month. Typical homework assignments include evaluating the accuracy of automatic thoughts and beliefs. It is important for the therapist to realize that the thoughts a person has about a problem are not beliefs. In CBT, the therapist helps the patient identify the underlying belief, and then they

- explore the evidence that supports or refutes the belief about the event,
- identify alternative explanations for the event, and
- examine the real implications if the belief is true. (e.g., “What is the worst thing that could happen?”)

In the sessions, the therapist challenges negative beliefs and helps the patient examine the “self-talk” that helps to sustain these beliefs. Cognitive techniques focus on the patient’s patterns of automatic thinking, first identifying what they are by examining the patient’s recurrent patterns in everyday life and then testing the validity of these automatic thoughts.

Other tools that are used to help change the patient’s self-perception include bibliotherapy (the use of books that offer alternative thoughts and responses), journaling, and keeping a diary focused on emotional and behavioral responses to upsetting situations that documents small changes that might otherwise go unnoticed. The patient is also encouraged to make note of positive events and positive thoughts about themselves and their ability to cope with negative events. These positive thoughts and effective coping responses are reinforced in interactions with the therapist. As goals are developed at the beginning of each therapy session, the last few minutes are spent reviewing the progress toward the goals for that day.

Evaluation and Termination

Evaluation and termination begin with the original contract when patient and therapist determined the number of sessions. The patient's progress toward treatment goals is continually evaluated, and the patient is urged to become more self-reliant and independent. As progress is never a continuous upward process, therapists prepare the patient for setbacks by acknowledging that setbacks are normal and expected and crafting ways in which the patient can deal with them. It is not uncommon for the time between sessions to lengthen as the final session approaches. At the final session, the use of "booster" sessions is discussed. Frequently, a session is scheduled in 6 months to do a quick "check-up" and review continuing progress.

Strengths and Limitations of Cognitive Behavioral Therapy

One of the strengths of CBT lies in the body of empirical evidence supporting the effectiveness of these interventions (Possemato et al., 2018; Spoelstra et al., 2015). Many studies show positive, sustained improvement in people treated with this form of intervention. Critics, however, identify some limitations. Chief among the limitations identified is the concern that the therapeutic relationship, long believed to be the main factor in patient improvement, may be forgotten in the rigid adherence to specific techniques. Others believe that change is dependent on the patient developing a clear understanding of their belief system and the origin of that system; thus, CBT is not effective with persons who have thought disorders and other issues that interfere with the ability to do so.

Rational Emotive Behavior Therapy

KEYCONCEPT Rational emotive behavior therapy (REBT) is a psychotherapeutic approach that proposes that unrealistic and irrational beliefs cause many emotional problems. It is a form of CBT with a primary emphasis on changing irrational beliefs that cause emotional distress into thoughts that are more reasonable and rational.

REBT is based on the assumptions that people are born with the potential to be rational (self-constructive) and irrational (self-defeating). Ellis believes that

highly cognitive, active, directive homework assignments and structured therapies are likely to be more effective in a shorter time than other therapies. Irrational thinking, self-damaging habituations, wishful thinking, and intolerance are exacerbated by culture and family groups (Ellis et al., 2008).

Rational Emotive Behavior Therapy Framework

The basic framework for REBT uses the acronym **ABCDE** (see [Box 13.2](#)).

BOX 13.2

The Rational Emotive Behavior Therapy Framework

1. Activating event that triggers automatic thoughts and emotions
2. Beliefs that underlie the thoughts and emotions
3. Consequences of this automatic process
4. Dispute or challenge unreasonable expectations
5. Effective outlook developed by disputing or challenging negative belief systems

The **activating event** may be either external or internal and not necessarily an actual event, but it may also be an emotion or a thought/expectation. For example, a person who is lonely and feels isolated but is uncomfortable in interpersonal situations may see a flyer advertising a gathering of people who are interested in discussing solutions to global warming and would really like to attend (**Activating event**). However, when this person thinks about going to the gathering, they imagine going into the room where they do not know anybody and someone trying to engage them in conversation. Their imagination provides a picture of not being able to respond and leaving the room after suffering great embarrassment (**Belief system**: “I am a failure in social situations, and everybody can see what a loser I am.”). Of course, he decides not to go (**Consequences of his belief system**).

Belief systems are shaped by rationality, which is self-constructive, and irrationality, which is self-defeating. Rational beliefs are flexible and lead to reasonable evaluations of negative activating events. For example, after a low grade on an examination, instead of believing “I am stupid” or “that instructor is out to get me,” student might conclude that “I earned a low grade on the test; I

really need to work to develop a better understanding of the content,” or “I think I need to get help with my test-taking skills.” Other rational beliefs might be “I really didn’t have time to study; so, I can accept this grade and just move on.” In other words, “I don’t like it, but I can live with it.” Rational beliefs accept that human beings are fallible and reject absolutes such as always and never.

Irrational beliefs promote dysfunctional negative emotions that in turn lead to psychic pain and discomfort. Behaviors directed at relief of this pain tend to be self-defeating: “I can’t fight the system; I will never succeed in this class.” There are five themes common in irrational beliefs:

1. A demand: “This *must* happen.”
2. Absolute thinking: “All or nothing at all.”
3. Catastrophizing: Exaggerating negative consequences of an event.
4. Low frustration tolerance: Everything should be easy.
5. Global evaluations of human worth: “People can be rated, and some are better than others.”

Dysfunctional consequences of the interaction between A (activating event) and B (belief system) follow from absolute, rigid, and irrational beliefs whereas **functional consequences** follow from flexible and rational beliefs. For example, demands about self based on “musts” reinforce dysfunctional beliefs such as, “I must do well and be approved by significant others, and if I’m not, then it’s awful.” The consequences of these beliefs are often anxiety, depression, shame, and guilt that lead to the inability to develop or achieve life’s goals or to develop satisfying interpersonal relationships. Self-regard that is dependent on the approval of others demands that others “treat me fairly and considerately; it’s terrible I can’t bear it when you don’t.” Thus, when fairness and consideration are not forthcoming, passive-aggressiveness, anger, rage, and violence may erupt. Demands that the world or life be exactly as one wants can also lead to self-pity as well as problems of self-discipline and addictive behaviors.

Rational Emotive Behavior Therapy Interventions

REBT uses role-playing, assertion training, desensitization, humor, operant conditioning, suggestion, support, and other interventions. According to Ellis, there are two basic forms of REBT: general and preferential. General REBT is

synonymous with CBT and teaches patients rational and healthy behavior. Preferential REBT includes general REBT but also emphasizes a profound philosophic change. It teaches patients how to dispute irrational ideas and unhealthy behaviors and to become more creative, scientific, and skeptical thinkers (Ellis et al., 2008). The therapist uses the ABCDE model in a structured manner (Box 13.2>). A major challenge for the therapist is to teach the patient the difference between thoughts and beliefs. Automatic thoughts are not irrational beliefs but are inferences about the belief. The focus of interventions during the therapy sessions (frequently several weeks or months apart) is on developing rational beliefs to replace those that are irrational and interfere with the patient's quality of life. Figure 13.2 examines the sequence of treatment used in REBT.

Solution-Focused Brief Therapy

KEYCONCEPT Solution-focused brief therapy (SFBT) focuses on solutions rather than problems. This approach does not challenge the existence of problems but proposes that problems are best understood in relation to their solutions. Solution-focused therapy assists the client in exploring life without the problem (De Shazer, 1985; Miller & Berg, 1995).

SFBT, although basically a cognitive approach, differs in philosophy and approach from other cognitively based approaches. The primary difference is the de-emphasis on the patient's "problems," or symptoms, and an emphasis on what is functional and healthful. SFBT assists the patient in exploring life without the problem, and it asserts that what is expected to happen influences what the patient does. By discovering what future the client sees as worth striving for, the present becomes important to that future. Otherwise, there is no sense in the patient doing something different or seeing something in a different light. Empirical evidence exists that supports the use of solution-focused approaches (Franklin et al., 2017).

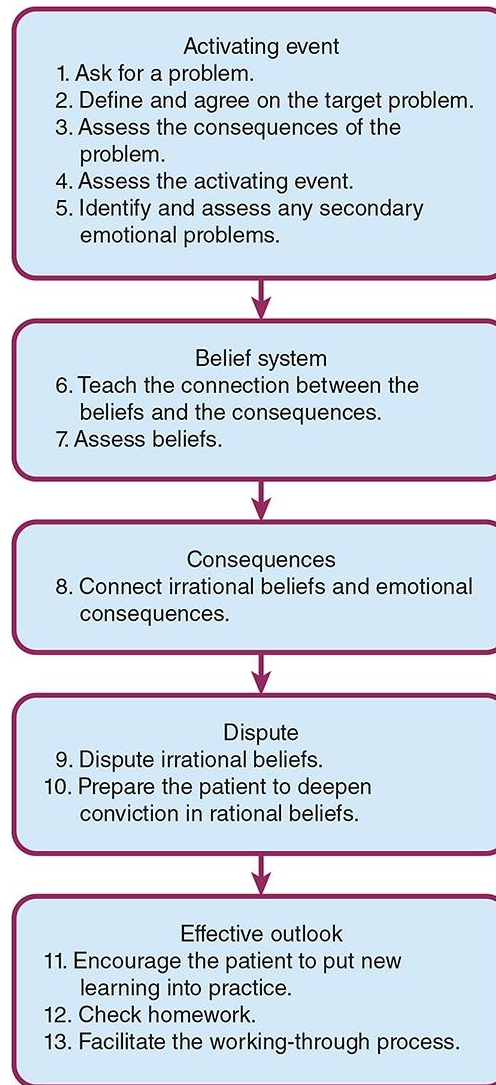

FIGURE 13.2 Rational emotive behavior therapy sequence of treatment.

Solution-focused theory views the patient as an individual with a collection of strengths and successes as opposed to a diagnosis and collection of symptoms. Solution-focused approaches emphasize the uniqueness of the individual and their capacity to make changes or to deal with their day-to-day lives despite what may seem to be the predominant pathology (Bond et al., 2014).

Solution-Focused Behavior Therapy Assumptions

SFBT assumes that change is constant and inevitable. Essentially, everyone

changes constantly and is never the same from 1 minute to the next. A person interacts, if only in a minute way, with a constantly changing environment. Very small changes can lead to larger changes, and the stimulus to change comes from a variety of sources. Constant change and its “ripple effect” direct the strategies and interventions used by the therapist. Both assumptions and strategies point the patient toward a positive, future-oriented change. [Box 13.3](#) lists the assumptions that underlie this approach.

BOX 13.3

Solution-Focused Behavior Therapy Assumptions

1. People have the strengths and resources needed to solve their problems; therefore, the therapist’s role is to recognize and emphasize these by amplifying them primarily through asking questions that enable a collaborative approach to constructing solutions.
2. It isn’t necessary to know a lot about the complaint and its origins or functions in order to resolve it.
3. Define and dissect the “problem” from the perspective of the patient and look for exceptions to the “problem” in the patient’s life.
4. Even long-standing issues can be resolved in a relatively short period of time.
5. There is no right or wrong way to see things.
6. Change is most likely to occur when the focus is on what is changeable.
7. The job of the therapist is to identify and amplify change and maintain a focus on the present and the future.
8. The therapist and patient cocreate reality, utilizing what the patient perceives is “truth,” and develop small, concrete, specific, and reality-based goals that are realistic in the context of the patient’s life.
9. The therapist expects change and movement and that expectation is inherent in the questions used and the attitude of the therapist.

Based on O’Hanlon, W. H., & Weiner-Davis, M. (2003). *In search of solutions: A new direction in psychotherapy*. W. W. Norton & Company.

Solution-Focused Behavior Therapy Interventions

In SFBT, the therapist takes a position of curiosity in learning about the patient, as opposed to an expert to whom the person has come to be helped. This curiosity is manifested in the questions and techniques that are integral to this approach and enable the development of realistic goals at each session. Questions used in eliciting the “problem” (frequently referred to as the “issue(s)” to avoid focusing on the “problem”) seek very specific information. Examples of questioning in the initial session might include the following:

1. What brought you here today?
2. What is going on that made you choose to seek help?
3. Give me a recent example of how that was demonstrated in your life.
4. Who was present when this happened? What did they say and do, and what did you say or do? And then what happened?
5. When does this kind of thing happen most often?
6. Where is it likely to occur?
7. Where is it least likely to occur?
8. Is there a particular time (of day, month, and year) when this is **unlikely** to happen?
9. How does this interfere with your life, your relationships, self-image, etc.?

If your partner/significant other/coworker were here now, how would they say that you were trying to solve the issue or problem?

Interventions in SFBT focus on achievement of specific, concrete, and achievable goals developed in the collaboration between therapist and patient. These goals, formed using the patient's language, are specific and focus on strengths. Primary techniques used to facilitate progress toward goal attainment are skillfully crafted questions that include the use of the "miracle question," exceptions, scaling, relationship questions, as well as the use of feedback, with an emphasis on complimenting any small, goal-oriented change the patient makes. Feedback conveys to the patient that the therapist has listened carefully and recognizes that working toward a goal of change is difficult and requires hard work.

In **miracle questions**, the therapist structures a scenario that the patient is asked to think about carefully (even though it sounds strange) and to use their imagination in crafting the response, again to very specific questions (see [Box 13.4](#) for a sample scenario and questions).

Other ways of facilitating a similar focus on what the solution would look like are to ask the patient to keep track of what goes well in their life that they would like to see happen again. The patient is encouraged to keep a written list of what they have noticed and bring it to the next session.

BOX 13.4

Miracle Questions

"I want you to pretend that tonight after you go to bed and are soundly asleep a miracle occurs. The

miracle is that the issues that have been bothering you and interfering in your life disappear. Since you have been asleep, you are not aware that the miracle has occurred when you wake up in the morning.”

1. What would be your first clue that something was different for you?
2. How will your life be different?
3. What will you be doing instead of _____?
4. How will you be doing this?
5. Beside yourself, who will be the first to notice that there is something different about you?
6. What will that person say or do?
7. How will you respond differently than you might if the issue or problem was still present?

Exception questions are rooted in the belief that nothing is constantly present at the same level of intensity, so that there are fluctuations on how the patient experiences “the problem.” Exception questions are used to help the patient identify times when they are not bothered by the issue or it causes less distress. The role of the therapist is then to amplify these times for the patient. Questions used to elicit exceptions may be as follows:

1. When do you not have that problem/issue?
2. How do you explain that the problem/issue doesn’t happen then?
3. What is different in those times, and what are you doing differently?
4. What has occurred that causes the problem/issue to happen more often?

Scaling questions are useful in making the patient’s problem or issue more specific, in quantifying the exceptions noted in intensity, and in tracking change over time. Scaling questions ask the patient to rate the issue or problem on a scale of 1 to 10, with 1 being the worst, or greatest intensity, and 10 being the complete absence of the issue. The therapist notes any change on the scale toward 10, asking the patient what was done to make that happen.

Relationship questions are used to amplify and reinforce positive responses to the other questions (see [Box 13.4](#)). Patients are asked to consider the point of view of the significant others in their lives. The use of relationship questions can expand the patient’s world and help to develop and maintain empathic relationships with others.

Compliments are affirmations of the patient. They reinforce the patient’s successes and the strengths needed to achieve those successes. For example, a patient who has frequently gotten into trouble because of a “bad” temper reports in a session that he almost got into an argument while standing in a supermarket checkout lane but instead walked away. An appropriate compliment by the therapist might be “Wow! That’s great. That must have been very difficult for

you.” Compliments can create hope in the patient.

NCLEXNOTE Application of knowledge from the social sciences such as psychology will underlie many of the psychosocial questions. Familiarity with the basic cognitive therapy models will strengthen the application of these concepts to patient situations.

USE OF COGNITIVE THERAPIES IN PSYCHIATRIC NURSING

The context of practice has changed considerably for psychiatric nurses. Length of stay for patients in inpatient settings is becoming shorter every year. The patients admitted to inpatient settings are acutely ill and dealing with more complex issues than ever before. More psychiatric care occurs in prisons than in psychiatric hospitals. More and more the focus of practice is in the community, private homes, and primary care settings rather than in specialty hospitals.

Inpatient Settings

Solution-focused therapy is one of the brief cognitive therapies used by psychiatric nurses in acute inpatient psychiatric settings. SFBT’s emphasis on strengths fits well with the values of psychiatric nurses, and the techniques used are well within their scope of practice. Solution-focused approaches have been effective with hospitalized people who were experiencing delusions, hallucinations, and/or loosening of associations (see [Box 13.5](#)>).

Other cognitive therapeutic techniques used in inpatient settings include journaling and “homework” assignments that focus on education about diagnoses and medications, as well as on group process. These interventions seem to work well in conjunction with shortened length of stay in inpatient settings.

Primary Care Settings

Cognitive interventions in primary care settings are useful and cost-effective. For example, insomnia in breast cancer survivors, depression, chronic pain, and

anxiety has been successfully treated with CBT (Bélanger et al., 2016; Gudenkauf et al., 2015; Shepardson et al., 2020). Researchers in the United Kingdom have reported 10% to 20% of hospital patients suffer from “health anxiety” that has responded well to interventions by nurses who were trained in 2-day workshops in the application of CBT skills. These positive results were sustained over a period of 2 years (Tyrer et al., 2014). Nurses in nonpsychiatric settings can learn the techniques of CBT that can be easily applied in hospital settings. Patient education about sleep hygiene and relaxation training can be used by nurses in any setting.

BOX 13.5

Trauma-Informed Care and Brief Solution-Focused Therapy

Aremu, B., Hill, P. D., McNeal, J. M., Petersen, M. A., Swanberg, D., & Delaney, K. R. (2018). Implementation of trauma-informed care and brief solution-focused therapy: A quality improvement project aimed at increasing engagement on an inpatient psychiatric unit. Journal of Psychosocial Nursing and Mental Health Services, 56(8), 16–22.

THE QUESTION: After receiving training on trauma-informed care and brief solution-focused therapy approach, are nurses able to use patient engagement techniques in brief solution-focused therapy, and will the use of PRN medications for de-escalation be reduced?

METHODS: This quality improvement project occurred on a 25-bed acute psychiatric unit. Staff received education on patient engagement and new staff were educated on their role in creating and maintaining a trauma-informed care organization, building trusting relationships, and creating a safe, healing environment. A total of 33 staff participated in one of two educational sessions. The Management of Aggression and Violence Attitude Scale measured staff comfort when handling aggression and engaging clients during de-escalation. The Combined Assessment of Psychiatric Environments–brief version measured staff engagement and patient experience of care on inpatient psychiatric units. These tools were administered pre- and post (1 and 3 months) education for a change in engagement and knowledge. PRN usage was measured at pre- and post-education. Patient records were audited for use of SBFT techniques.

FINDINGS: While there was improvement in all of the measures, the use of PRN medications declined, and the patient records showed that SBFT approaches were being used, the measures did not reach the level of significance.

IMPLICATIONS FOR NURSING: Changing nursing practice takes time. Quality improvement projects can be useful in shaping nursing practices even though the results may not reach the level of significance.

Community Settings

In community settings, cognitive approaches are used in combination with a broad array of interpersonal, behavioral, educational, and pharmacologic interventions. Cognitive interventions are used within a holistic evaluation of patients that includes a complete health history and physical examination and evaluation of possible co-occurring disorders such as depression and alcohol and other drug use or abuse. In particular, the use of questioning such as that integral to solution-focused approaches elicits strengths in a relatively short time and can provide a means for the nurse to support positive coping. The focus on realistic goal development provides a means of evaluation of patient progress.

Home settings are also conducive to the implementation of cognitive techniques. Small, concrete, specific goals developed in a naturalistic setting such as the home can create significant change for the whole family. CBT and SFBT approaches are very useful in primary care settings where time with patients is very short. Goal setting, use of scaling questions, and compliments can be done in the course of a 15-minute interaction.

SUMMARY OF KEY POINTS

- Cognitive therapies have a long history in mental health care and have support as evidence-based interventions effective in several mental disorders.
- Psychiatric nurses use cognitive interventions in a variety of settings. Cognitive therapies serve as the framework for psychotherapy as well as interdisciplinary treatment.
- CBT focuses on dysfunctional thinking through the examination of the cognitive triad, cognitive distortions, and schema.
- REBT assumes that people are born with the tendency to be rational and irrational. Using the ABCDE framework, REBT focuses on identifying and changing irrational beliefs that lead to negative consequences.
- SFBT identifies the possible solutions before addressing the problem.

CRITICAL THINKING CHALLENGES

1. Compare and contrast the three cognitive therapies in terms of assumptions and interventions.
2. A patient has recently been fired from her job, which is the third job that she has had within 1 year. She is depressed but denies suicidal thoughts. She tells you that she is a failure and can never get and keep a job. Discuss how CBT, REBT, and SFBT would view and treat this patient.
3. A nurse manager plans to use CBT as a theoretical model for an inpatient unit. Discuss the interventions that should be used on an inpatient unit that applies the CBT model.

Group Interventions

Mary Ann Boyd

KEYCONCEPTS

- group
- group dynamics
- group process

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Discuss concepts used in leading groups.
2. Compare the roles that group members can assume.
3. Identify important aspects of leading a group, such as member selection, leadership skills, seating arrangements, and ways of dealing with challenging behaviors of group members.
4. Distinguish types of groups: psychoeducation, support, psychotherapy, and self-help.
5. Describe common nursing intervention groups.

KEY TERMS

- Closed group
- Cohesion
- Coleadership
- Communication pathways
- Direct leadership
- Dyad
- Formal group roles
- Group themes
- Groupthink
- Indirect leadership
- Individual roles
- Informal group roles
- Maintenance roles
- Open group
- Task roles
- Triad

INTRODUCTION

Group interventions are a key nursing strategy in mental health promotion and recovery. A group experience can help an individual enhance self-understanding, conquer unwanted thoughts and feelings, and learn new behaviors. In a group, members learn from each other as well as the leader. Group interventions are efficient because several patients can participate at one time, and they can be

used in most settings. Groups can vary in purpose from being a social group attending a local ball game to an intensive psychotherapy group.

Group interventions are not unique to mental health but are used universally in all aspects of the health care system. For example, web-based psychoeducational groups were used with first-time mothers (Jiao et al., 2019); persons with head and neck cancer (Richardson et al., 2019); and caregivers (Frias et al., 2020). Group interventions are delivered in several formats including face-to-face, virtual, and mobile applications. Digital group interventions are being tested and are expected to stay mainstream even after the coronavirus threat decreases. Digital reminiscence therapy can help people with dementia improve their mood and increase opportunities to engage with other people (Moon & Park, 2020).

KEYCONCEPT A **group** is two or more people who develop interactive relationships and share at least one common goal or issue. *A group is more than the sum of its parts* A group develops its own personality, patterns of interaction, and rules of behavior.

Nurses in various roles and settings use group interventions, such as when conducting patient education or leading support groups. This chapter discusses group concepts, considerations in group leadership, and types of groups that nurses commonly lead.

PREPARING TO LEAD A GROUP

Psychiatric nurses lead a wide range of groups (see later discussion of Types of Groups). Some are structured such as a psychoeducation group, and others are unstructured (e.g., a social group). Groups can be face-to-face groups or virtual groups. The virtual groups may be synchronous or asynchronous. The purpose of the group will dictate the amount of structure and types of activities. In all groups, nurses maintain professional boundaries. Because some group activities are social in nature (unit parties, community trips), it is easy to forget that socialization is a treatment intervention. Nurses should avoid meeting personal social needs within this context.

Thoughtful planning and preparation make for a successful group. Confidentiality is important in all groups. The following sections discuss important considerations when planning for a group.

Virtual Group Interventions

Offering a virtual group has the advantage of being efficient and convenient, but there are also real challenges when planning the group. For example, is the software new or is the person already using it? Software should be Health Insurance Portability and Accountability Act compliant, which may necessitate purchase of new software. Do all of the potential group members have access to the internet recognizing that the strength varies by location? What will it cost, and will the virtual group fit in with your workflow? For example, face-to-face inpatient group require less preparation time.

During the COVID-19 nationwide public health emergency, the social distancing requirements have increased the use of virtual groups replacing in-person, face-to-face groups such as support and substance use groups. The importance of engagement becomes more challenging as members may not be as actively engaged in the virtual groups as the face-to-face groups (Colditz et al., 2020). The leader must additional strategies to engage and motivate the members to engage and participate in the group.

Selecting Members

Individuals can self-refer or be referred to a group by treatment teams or clinicians, but the leader is responsible for assessing each individual's suitability for the group. One factor to consider is sociodemographic similarity, especially when forming a larger group. Research shows that there is a higher probability of attendance in larger groups, when members were similar in age and ethnicity (Firth et al., 2020). The individual's suitability for the group can be based on the following criteria:

- Does the purpose of the group match the needs of the potential member?
- Does the potential member have the social skills to function comfortably in the group?
- Will the other group members accept the new group member?
- Can the potential member make a commitment to attending group meetings?

Forming an Open or Closed Group

In planning for a group, one of the early decisions is whether the group will be open or closed. In an **open group**, new members may join, and old members may leave the group at different sessions. Because length of patient hospitalization is relatively short, open groups are typical of inpatient units. For example, a newly admitted patient may join an anger management group that is part of an ongoing program in an inpatient unit.

In a **closed group**, members begin the group at one time, and no new members are admitted. If a member leaves, no replacement member joins. In a closed group, participants get to know one another very well and can develop close relationships. Closed groups are more typical of outpatient groups that have a sequential curriculum or psychotherapy groups. These groups usually meet weekly for a specified period. Outpatient smoking cessation, psychotherapy, and psychoeducation groups are examples.

Determining Composition

Another decision is the group size. The size of a group will depend on the overall group goals and patients' abilities. Patients with challenging behaviors should be carefully screened and may be able to function in smaller rather than larger groups.

Small groups (usually no more than seven to eight members) become more cohesive, are less likely to form subgroups, and can provide a richer interpersonal experience than large groups (Yalom & Leszcz, 2005). A very small group is two people (**dyad**) or three (**triad**). Small groups function nicely with one group leader although many small groups are led by two people. Although small groups cannot easily withstand the loss of members, they are ideal for patients who are highly motivated to deal with complex emotional problems, such as sexual abuse, eating disorders, or trauma or for those who have cognitive dysfunction and require a more focused group environment with minimal distractions.

In leading a small group, the leader gets to know the members very well but maintains objectivity. The nurse observes for transference of participants toward the leader or other member. If a member becomes a "favorite patient," the leader

should reflect upon any underlying personal countertransference issues (see [Chapter 10](#)).

NCLEXNOTE Be prepared to select members and plan for a patient or family support group to help deal with the impact of mental illnesses on the family lifestyle.

Large groups (more than 8–10 members) are effective for specific problems or issues, such as smoking cessation or medication information. Large groups are often used in the workplace for health promotion activities such as smoking cessation, healthy eating, and meditation. A large group can be ongoing and open ended. Usually, transference and countertransference issues do not develop.

However, leading a large group is challenging because of the number of potential interactions and relationships that can form and the difficulty in determining the feelings and thoughts of the participants. As the size of the group increases, the level of engagement decreases and conflict increases (Wu et al., 2020). It may be difficult to get everyone's attention to begin a group session. Subgroups can form, making it difficult to develop a cohesive group. If subgroups form that are detrimental to the group, the nurse can change the structure and function of communication within the subgroups by rearranging seating and encouraging the subgroup to interact with the rest of the group. Gender mix is also a consideration and can make a difference in the success of the group. It is important to avoid making assumptions about the gender of your group members. Asking members for their personal pronouns will set the stage for using gender-inclusive interactions.

SELECTING A LEADERSHIP STYLE

A group is led within the context of the group leader's theoretic background and the group's purpose. For example, a leader with training in cognitive-behavioral therapy may focus on treating depression by asking members to think differently about situations, which in turn lead to feeling better. A leader with a psychodynamic orientation may focus on the feelings of depression by examining situations that generate the same feelings. Whatever the leader's theoretic background, their leadership behavior can be viewed on a continuum of direct to indirect.

Direct leadership behavior enables the leader to control the interaction by

giving directions and information and allowing little discussion. The leader literally tells the members what to do. On the other end of the continuum is **indirect leadership**, in which the leader primarily reflects the group members' discussion and offers little guidance or information to the group. Sometimes, the group needs a more direct approach, such as in a psychoeducation class; other times, it needs a leader who is indirect. The challenge of providing leadership is to give sufficient direction to help the group meet its goals and develop its own group process but enough freedom to allow members to make mistakes and recover from their thinking errors in a supportive, caring, and learning environment.

Coleadership, when two people share responsibility for leading the group, is useful in most groups if the coleaders attend all sessions and maintain open communication. Coleadership works well when the coleaders plan together and meet before and after each session to discuss the group process.

Setting the Stage: Arranging Seating in a Face-to-Face Group

Group sessions should be held in a quiet, pleasant room with adequate space and privacy. Holding a session in too large or too small room inhibits communication. The sessions should be held in private rooms that nonmembers cannot access. Interruptions are distracting and can potentially compromise confidentiality. Arrangement of chairs should foster interaction and reduce communication barriers. Communication flows better when no physical barriers, such as tables, are between members. Group members should be able to see and hear each other. Arranging a group in a circle with chairs comfortably close to one another without a table enhances group work. No one should sit outside the group. If a table is necessary, a round table is better than a rectangular one, which implicitly increases the power of those who sit at the ends.

Group members tend to sit in the same places. Those who sit close to the group leader are more likely to have more power in the group than those who sit far away.

SETTING THE STAGE: ARRANGING FOR A

VIRTUAL GROUP

Virtual groups are becoming common as the availability and accessibility of platforms (e.g., Microsoft Teams, Zoom, etc.) increases. To participate, patients must have internet access and devices that are compatible with the platform. Ideally, group members who are in synchronous groups have video, as well as audio capability. Groups members should be able to see each other. In asynchronous groups, the members respond to discussion usually through typing their responses. The group leader provides specific directions related to time and date of meeting and accessing the group.

Planning the First Meeting

The leader sets the tone of the group at the first meeting. The leader and members introduce themselves. The leader may ask participants to share some introductory information such as why they joined the group and what do they hope to gain from the experience. The leader can share name, credentials for leading group, and a brief statement about experience. The leader should avoid self-disclosing personal information.

The first session is the time to explain the structure of group, including the purpose and group rules (Box 14.1>). It is important the group starts and ends at scheduled times; otherwise, members who tend to be late will not change their behavior, and those who are on time will resent waiting for the others. The leader also explains when and if new members can join the group.

BOX 14.1

Example of Group Guidelines

- Group sessions begin and end on time.
- All views are heard and respected. Cell phones are silenced; there are no side conversations.
- Only one person speaks at a time. No interrupting.
- Emotion is acceptable; aggression is not. Disagreements should be expressed calmly and objectively.
- Everyone is expected to stay for the entire meeting.
- Who we see and what is said here stay here.

LEADING A GROUP

During the first session, the leader begins to assess the group dynamics or interactions—both verbal and nonverbal. During the group sessions, these interactions will be important in understanding the group process and may determine the success of the group.

Group Dynamics

KEYCONCEPT Group dynamics are the verbal and nonverbal interactions that occur in the group.

The theoretical basis of group dynamics is attributed to Kurt Lewin (1939) and proposes that by joining a group, one's interactions with fellow members change the individual and the other group members; in addition, a highly attractive group can exert influence on its members, and a weak group does not have the same ability (Leach et al., 2019).

As a group develops its unique characteristics, individual members become connected to each other and are included in the group. The group's personality, pattern of interaction, and behavior become primary. Whether individual members are included in the group will depend on how the group treats that individual. Inclusion is also dependent upon whether the individual is motivated to be included. That is, inclusion is a two-way street. If the group's goals are consistent with individual members' goals and members are motivated to participate in the group, the group is more likely to be well attended and successful (Jansen et al., 2020).

Group Process

A group leader is responsible for monitoring and shaping the group process, as well as focusing on the group content. Although models of group development differ, most follow a pattern of a beginning, middle, and ending phase ([Table 14.1](#)) (Corey et al., 2018). These stages should not be viewed as a linear progression with one preceding another but as a dynamic process that is

constantly revisiting and reexamining group interactions and behaviors, as well as progressing forward. The group leader needs to be aware of the group's stage of development as well as leadership responsibilities.

KEYCONCEPT **Group process** is the development and culmination of the session-to-session interactions of the members that move the group toward its goals.

Stages of Group Development

Beginning Stage: The Honeymoon

In the beginning, the group leader acknowledges each member; constructs a working environment; develops rapport with the members; begins to build a therapeutic relationship; and clarifies outcomes, processes, and skills related to the group's purpose (Corey et al., 2018). To carry out these functions, the leader processes group interactions by staying objective and observing members' interactions as well as participating in the group. The leader reflects on, evaluates, and responds to interactions. The use of various techniques enhances the leader's ability to lead the group effectively and to help the group meet its goals (Table 14.2).

TABLE 14.1 COMPARISON OF MODELS OF GROUP DEVELOPMENT

Phase	Robert Bales (1955)	William Schutz (1960)	Bruce Tuckman (1965)
Beginning	<ul style="list-style-type: none"> • <i>Orientation:</i> What is the problem? 	<ul style="list-style-type: none"> • <i>Inclusion:</i> Deal with issues of belonging and being in and out of the group. 	<ul style="list-style-type: none"> • <i>Forming:</i> Get to know one another and form a group.
Middle	<ul style="list-style-type: none"> • <i>Evaluation:</i> How do we feel about it? 	<ul style="list-style-type: none"> • <i>Control:</i> Deal with issues of authority (who is in charge?), dependence, and autonomy. 	<ul style="list-style-type: none"> • <i>Storming:</i> Tension and conflict occur; subgroups form and clash with one another. • <i>Norming:</i> Develop norms of how to work together.
Ending	<ul style="list-style-type: none"> • <i>Control:</i> What should we do about it? 	<ul style="list-style-type: none"> • <i>Affection:</i> Deal with issues of intimacy, closeness, and caring versus dislike and distancing. 	<ul style="list-style-type: none"> • <i>Performing:</i> Reach consensus and develop cooperative relationships.

Source: Bales, R. (1955). A set of categories for the analysis of small group interaction. *American Sociological Review*, 15, 257–263; Schutz, W. (1960). *FIRO: A three-dimensional theory of interpersonal behavior*. Holt, Rinehart & Winston; Tuckman, B. (1965). Developmental sequence in small groups. *Psychological Bulletin*, 63(6), 384–399.

During beginning sessions, group members get to know one another and the group leader. The length of the beginning stage depends on the purpose of the group, the number of members, and the skill of the leader. It may last for only a few sessions or several. Members often exhibit polite, congenial behavior typical of those in new social situations. They are “good patients” and often intellectualize their problems; that is, these patients deal with emotional conflict or stress by excessively using abstract thinking or generalizations to minimize disturbing feelings. Members are usually anxious and sometimes display behavior that does not truly represent their feelings.

In this phase, members begin to test whether they can trust one another and the leader. Members may come late to group or try to extend group time. Sometime after the initial sessions, group members usually experience a period of conflict, either among themselves or with the leader. This conflict is a normal part of group development, and many believe that conflict is necessary to move into any working phase. Sometimes, one or more group members become the scapegoat. Such situations challenge the leader to guide the group during this period by avoiding taking sides and treating all members respectfully.

Table 14-2: Techniques in Leading Groups

Technique	Purpose	Example
Support: giving feedback that provides a climate of emotional support	Helps a person or group continue with ongoing activities Informs group about what the leader thinks is important Creates a climate for expressing unpopular ideas Helps the more quiet and fearful members speak up	“We really appreciate your sharing that experience with us. It looked like it was quite painful.”

<i>Confrontation:</i> challenging a participant (needs to be done in a supportive environment)	<p>Helps individuals learn something about themselves</p> <p>Helps reduce some forms of disruptive behavior</p> <p>Helps members deal more openly and directly with one another</p>	<p>“Tom, this is the third time you have changed the subject when we have talked about spouse abuse. Is something going on?”</p>
<i>Advice and suggestions:</i> sharing expertise and knowledge that the members do not have	<p>Provides information that members can use after they have examined and evaluated it</p> <p>Helps focus the group’s task and goals</p>	<p>“The medication you are taking may be causing you to be sleepy.”</p>
<i>Summarizing:</i> statements at the end of sessions that highlight the session’s discussion, any problem resolution, and unresolved problems	<p>Provides continuity from one session to the next</p> <p>Brings to focus still unresolved issues</p> <p>Organizes the past in ways that clarify; brings into focus themes and patterns of interaction</p>	<p>“This session, we discussed Sharon’s medication problems, and she will be following up with her physicians.”</p>
<i>Clarification:</i> restatement of an interaction	<p>Checks on the meanings of the interaction and communication</p> <p>Avoids faulty communication</p> <p>Facilitates focus on substantive issues rather than allowing members to be sidetracked into misunderstandings</p>	<p>“What I heard you say was that you are feeling very sad right now. Is that correct?”</p>

<i>Probing and questioning:</i> a technique for the experienced group leader that asks for more information	<p>Helps members expand on what they were saying (when they are ready to)</p> <p>Gets at more extensive and wider range of information</p> <p>Invites members to explore their ideas in greater detail</p>	“Could you tell us more about your relationship with your parents?”
<i>Repeating, paraphrasing, highlighting:</i> a simple act of repeating what was just said	<p>Facilitates communication among group members</p> <p>Corrects inaccurate communication or emphasizes accurate communication</p>	<p><i>Member:</i> “I forgot about my wife’s birthday.”</p> <p><i>Leader:</i> “You forgot your wife’s birthday.”</p>
<i>Reflecting feelings:</i> identifying feelings that are being expressed	<p>Orients members to the feelings that may lie behind what is being said or done</p> <p>Helps members deal with issues they might otherwise avoid or miss</p>	“You sound upset.”
<i>Reflecting behavior:</i> identifying behaviors that are occurring	<p>Gives members an opportunity to see how their behavior appears to others and to evaluate its consequences</p> <p>Helps members to understand others’ perceptions and responses to them</p>	“I notice that when the topic of sex is brought up, you look down and shift in your chair.”

Working Stage

The working stage of groups involves a real sharing of ideas and the development of closeness. A group personality may emerge that is distinct from the individual personalities of its members. The group develops norms, which are rules and standards that establish acceptable behaviors. Some norms are formalized, such as beginning group on time, but others are never really formalized, such as sitting in the same place each session. These normative standards encourage conformity and discourage behavioral deviations from the established norms. A member quickly learns the norms or is ostracized.

During this stage, the group realizes its purpose. If the purpose is education, the participants engage in learning new content or skills. If the aim of the group is to share feelings and experiences, these activities consume group meetings. During this phase, the group starts on time, and the leader often needs to remind members when it is time to stop.

Termination Stage or Saying Goodbye

Termination can be difficult for a group, especially an effective one. During the final stages, members begin to grieve for the loss of the group's closeness and begin to reestablish themselves as individuals. Individuals terminate from groups as they do from any relationship. One person may not attend the last session, another person may bring up issues that the group has already addressed, and others may demonstrate anger or hostility. Most members of successful groups are sad as the group terminates. During the last meetings, members may make arrangements for meeting after group. These plans rarely materialize or continue. Leaders should recognize these plans as part of the farewell process—saying goodbye to the group.

In terminating a group, the nurse discusses and summarizes the work of the group, including the accomplishments of members and their future plans. The nurse focuses on ending the group and avoids being pulled into working stage issues. For example, when a patient brings up an issue that was once resolved, the nurse reinforces the skills and then reminds the member of the actions that will be taken after the group has ended.

Facilitating Group Communication

One of the responsibilities of the group leader is to facilitate both verbal and nonverbal communication to meet the treatment goals of the individual members and the entire group. Because of the number of people involved, developing trusting relationships within groups is more complicated than developing a single relationship with a patient. The communication techniques used in establishing and maintaining individual relationships are the same for groups, but the leader also attends to the communication patterns among the members.

Encouraging Interaction

The nurse leads the group during this phase by encouraging interaction among members and being responsive to their comments. Active listening enables the leader to process events and track interactions. The nurse can then formulate responses based on a true understanding of the discussion. A group leader who listens also models listening behavior for others, helping them improve their skills. Members may need to learn to listen to one another, track discussions without changing the subject, and not speak while others are talking. At the end of the session, the nurse summarizes the work of the session and projects the work for the next meeting.

The leader maintains a neutral, nonjudgmental style and avoids showing preference to one member over another. This may be difficult because some members may naturally seek out the leader's attention or ask for special favors. These behaviors are divisive to the group, and the leader should discourage them. Other important skills include providing everyone with an opportunity to contribute and respecting everyone's ideas. A leader who truly wants group participation and decision-making does not reveal their beliefs.

Monitoring Verbal Communication

Group interaction can be viewed as a communication network that becomes patterned and predictable. In a group, verbal comments are linked in a chain formation. Monitoring verbal interactions and leading a group at the same time is difficult for one person. If there are two leaders, one may be the active leader of the group, and the other may sit outside the group and observe and record

rather than participating. If all members agree, the leader can use an audio or video recorder for reviewing interaction after the group session.

Interesting interaction patterns can be observed and analyzed (Fig. 14.1). By analyzing the content and patterns, the leader can determine the existence of **communication pathways**—who is most liked in the group, who occupies a position of power, what subgroups have formed, and who is isolated from the group. People who sit next to each other tend to communicate among themselves. Usually, those who are well liked, or display leadership abilities, tend to be chosen for interactions more often than do those who are not. The leader can also determine if there is a change of subject when a sensitive topic is introduced.

Deciphering Content Themes

Group themes are the collective conceptual underpinnings of a group and express the members' underlying concerns or feelings regardless of the group's purpose. Themes that emerge in groups help members to understand group dynamics. Different groups have different themes. A grief group most likely would have a theme of loss or new beginnings and an adolescent group may have a theme of independence. Although some predictable themes occur in groups, the obvious or assumed themes at the beginning may actually wind up differing from reality as the process continues. In one hospice support group, the members seemed to be focusing on the memories of their loved ones. However, upon examination of the content of their interactions, discussions were revolving around financial planning for the future (Box 14.2>).

Figure 14-1: Sociometric analysis of group behavior. In this sociometric structure, response pattern was recorded during member interaction. Group members interacted with number 1 the most. Therefore, number 1 is the over-chosen person. Numbers 5 and 7 are under chosen. Number 2 is never chosen and is determined to be the isolate.

Monitoring Nonverbal Communication

Observing nonverbal communication contributes to understanding the group dynamics. Members communicate nonverbally with each other, not only the group leader. Eye contact, posture, and body gestures of one member impact other members. For example, if one member is explaining a painful experience and another member looks away and tries to engage still another, the self-disclosing member may feel devalued and rejected because the disruptive behavior is interpreted as disinterest. However, if the leader interprets the disruptive behavior as anxiety over the topic, they may try to engage the other member in discussing the source of the anxiety.

The leaders should monitor the nonverbal behavior of group members during each session. Often, one or two people can set the overall mood of the group. Someone who comes to a session very sad or angry can set a tone of sadness or anger for the whole group. An astute group leader recognizes the effects of an individual's mood on the total group. If the purpose of the group is to deal with emotions, the group leader may choose to discuss the member's problem at the beginning of the session. The leader, thus, limits the mood to the one person experiencing it. If the group's purpose is inconsistent with self-disclosure of personal problems, the nurse should acknowledge the individual member's distress and offer a private session after the group. In this instance, the nurse would not encourage repeated episodes of self-disclosure from that member or others.

BOX 14.2

Group Themes

A large symptom management group is ongoing at a psychiatric facility. It is coled by two nurses who are skilled in directing large groups and knowledgeable about the symptoms of mental disorders. Usually, 12 people attend. The usual focus of the group is on identifying symptoms that indicate an impending

reemergence of psychotic symptoms, medication side effects, and managing the numerous symptoms that medication is not controlling.

The nurses identified the appearance of the theme of powerlessness based on the following observations:

- **Session 1:** T. L. expressed his frustration at being unable to keep a job because of his symptoms. The rest of the group offered their own experiences of being unable to work.
- **Session 2:** C. R. is late to group and announces that she was late because the bus driver forgot to tell her when to get off, and she missed her stop. She is irritated with the new driver.
- **Session 3:** N. T. is out of medication and says that he cannot get more because he is out of money again. He asks the nurses to lend him some money and make arrangements to get free medication.
- **Session 4:** G. M. relies on his family for all transportation and refuses to use public transportation.

In all of these sessions, participants expressed feelings that are consistent with loss of power.

Tracking Group Communication

The leader tracks the verbal and nonverbal interactions throughout the group sessions. Depending on the group's purpose, the leader may or may not share the observations with the group. For example, if the purpose of the group is psychoeducation, the leader may incorporate the information into a lesson plan without identifying any one individual. If the purpose of the group is to improve the self-awareness and interaction skills of members, the leader may point out the observations. The leader needs to be clear about the purpose of the group and tailor leadership strategies accordingly.

Determining Roles of Group Members

There are two official or **formal group roles**, the leader and the members; however, there are also important **informal group roles** or positions with implicit rights and duties that can either help or hinder the group's process. Ideally, one or more members assume **task roles** or functions. These individuals are concerned about the purpose of the group and "keep things on task." For example, *information seeker* is the member who asks for clarification; the *coordinator* spells out relationships among ideas, and the *recorder* keeps the minutes.

Maintenance roles or functions are assumed by those who help keep the group together. Other members assume maintenance roles and make sure that the group members get along with each other and try to make peace if conflict erupts.

These individuals are as interested in maintaining the group's cohesiveness as focusing on the group's tasks. The *harmonizer*, *compromiser*, and *standard setter* are examples of maintenance roles.

Both task and maintenance functions are needed in an effective group. In selecting members and analyzing the progress of the group, the leader pays attention to the balance between the task and maintenance functions. If too many group members assume task functions and too few assume maintenance functions, the group may have difficulty developing **cohesion**, or sticking together. If too many members assume maintenance functions, the group may never finish its work.

Individual roles are played by members to meet personal needs, such as feeling important or being an expert on a subject. These roles have nothing to do with the group's purpose or cohesion and can detract from the group's functioning (Box 14.3>). If individual roles predominate, the group may be ineffective.

Dealing with Challenging Group Behaviors

Problematic behaviors occur in all groups. They can be challenging to the most experienced group leaders and frustrating to new leaders. In dealing with any problematic behavior or situation, the leader must remember to support the integrity of the individual members and the group as a whole.

BOX 14.3

Roles and Functions of Group Members

TASK ROLES

- *Initiator-contributor* suggests or proposes new ideas or a new view of the problem or goal.
- *Information seeker* asks for clarification of the values pertinent to the group activity.
- *Information giver* offers “authoritative” facts or generalizations or gives own experiences.
- *Opinion giver* states belief or opinions with emphasis on what should be the group's values.
- *Elaborator* spells out suggestions in terms of examples, develops meanings of ideas and rationales, and tries to deduce how an idea would work.
- *Coordinator* shows or clarifies the relationships among various ideas and suggestions.
- *Orienter* defines the position of the group with respect to its goals.
- *Evaluator-critic* measures the outcome of the group against some standard.
- *Energizer* attempts to stimulate the group to action or decision.
- *Procedural technician* expedites group movement by doing things for the group such as distributing copies and arranging seating.
- *Recorder* writes suggestions, keeps minutes, and serves as group memory.

MAINTENANCE ROLES

- *Encourager* praises, agrees with, and accepts the contributions of others.
- *Harmonizer* mediates differences among members and relieves tension in conflict situations.
- *Compromiser* operates from within a conflict and may yield status or admit error to maintain group harmony.
- *Gatekeeper* attempts to keep communication channels open by encouraging or facilitating the participation of others or proposes regulation of the flow of communication through limiting time.
- *Standard setter* expresses standards for the group to achieve.
- *Group observer* keeps records of various aspects of group processes and interprets data to group.
- *Follower* goes along with the movement of the group.

INDIVIDUAL ROLES

- *Aggressor* deflates the status of others; expresses disapproval of the values, acts, or feelings of others; attacks the group or problem; jokes aggressively; and tries to take credit for the work.
- *Blocker* tends to be negative and resistant, disagrees and opposes without or beyond “reason,” and attempts to bring back an issue after group has rejected it.
- *Recognition seeker* calls attention to self through such activities as boasting, reporting on personal achievements, or acting in unusual ways.
- *Self-confessor* uses group setting to express personal, non-group-oriented feelings or insights.
- *Playboy* makes a display of lack of involvement in group’s processes.
- *Dominator* tries to assert authority or superiority in manipulating the group or certain members of the group through flattery, being directive, or interrupting others.
- *Help-seeker* attempts to call forth sympathy from other group members through expressing insecurity, personal confusion, or depreciation of self beyond reason.
- *Special interest pleader* speaks for a special group, such as “grass roots,” usually representing personal prejudices or biases.

Monopolizer

Some people tend to monopolize a group by constantly talking or interrupting others. This behavior is common in the beginning stages of group formation and usually represents anxiety that the member displaying such behavior is experiencing. Within a few sessions, this person usually relaxes and no longer attempts to monopolize the group. However, for some people, monopolizing discussions is part of their normal personality and will continue. Other group members usually find the behavior mildly irritating in the beginning and extremely annoying as time passes. Members may drop out of the group to avoid that person. The leader needs to decide if, how, and when to intervene. The best-case scenario is when savvy group members remind the monopolizer to let

others speak. The leader can then support the group in establishing rules that allow everyone the opportunity to participate. However, the group often waits for the leader to manage the situation. There are a couple of ways to deal with the situation. The leader can interrupt the monopolizer by acknowledging the member's contribution but redirecting the discussion to others, or the leader can become more directive and limit the discussion time per member.

“Yes, But ...”

Some people have a patterned response to any suggestions from others. Initially, they agree with suggestions others offer them, but then they add “yes, but ...” and give several reasons why the suggestions will not work for them. Leaders and members can easily identify this patterned response. In such situations, it is best to avoid problem-solving for the member and encourage the person to develop their own solutions. The leader can serve as a role model of the problem-solving behavior for the other members and encourage them to let the member develop a solution that would work specifically for them.

Disliked Member

In some groups, members clearly dislike one member. This situation can be challenging for the leader because it can result in considerable tension and conflict. This person could become the group's scapegoat. The group leader may have made a mistake by placing the person in this group, and another group may be a better match. One solution may be to move the person to a better matched group. Whether the person stays or leaves, the group leader must stay neutral and avoid displaying negative verbal and nonverbal behaviors that indicate that they too dislike the group member or are displeased with the other members for their behavior. Often, the group leader can manage the situation by showing respect for the disliked member and acknowledging their contribution. In some instances, getting supervision from a more experienced group leader is useful. Defusing the situation may be possible by using conflict resolution strategies and discussing the underlying issues.

The Silent Member

The engagement of a member who does not participate in group discussion can be challenging. This member has had a lifetime of being “the quiet one” and is usually comfortable in the silent role. The leader should respect the person’s silent nature. Like all the other group members, the silent member often gains a considerable amount of information and support without verbally participating. It is best for the group leader to get to know the member and understand the meaning of the silence before encouraging interaction.

Group Conflict

Most groups experience periods of conflict. The leader first needs to decide whether the conflict is a natural part of the group process or whether the group needs to address some issues. Member-to-member conflict can be handled through conflict resolution. Leader-to-member conflict is more complicated because the leader has the formal position of power. In this instance, the leader can use conflict resolution strategies but should be sensitive to the power differential between the leader’s role and the member’s role.

TYPES OF GROUPS

Psychoeducation Groups

The purposes of psychoeducation groups are to enhance knowledge, improve skills, and solve problems. The intervention strategies used in psychoeducation groups focus on transmission of information necessary for making some type of change and providing a process for making the change. Psychoeducation groups are formally planned, and members are purposefully selected. The group leader develops a lesson plan for each session that usually includes objectives, content outline, references, and evaluation tools. These groups are time limited and usually last for only a few sessions. If the group lasts longer than a few sessions, cohesiveness usually enhances outcomes, especially in those that teach health maintenance behaviors such as exercise and weight control (Brown, 2018).

There are a variety of psychoeducation groups, including recovery-oriented and mindfulness groups. Recovery-oriented groups facilitate consumer involvement in the educational process and build on the recovery principles (see [Chapters 2 and 9](#)). Examples of recovery-oriented groups include those that focus on how to manage a medication regimen or control angry outbursts. Group psychoeducation has changed perception of illness in persons with bipolar disorder, leading to an improvement in social functioning and improved self-esteem (Etain et al., 2018). Mindfulness groups are helpful in stress reduction.

Task Groups

Task groups focus on completion of specific activities, such as planning a week's menu. When members are strongly committed to completing a task and the leader encourages equal participation, cohesiveness promotes satisfaction and higher performance (Lockhart, 2017). To complete a task, group cohesiveness is especially important. Leaders can encourage cohesiveness by placing participants in situations that promote social interaction with minimal supervision, such as refreshment periods and team-building exercises.

Without cohesiveness, the group's true existence is questionable. In cohesive groups, members are committed to the existence of the group. In large groups, cohesiveness tends to be decreased, with subsequent poorer performance among group members in completing tasks. However, cohesiveness can be a double-edged sword. In very cohesive groups, members are more likely to transgress personal boundaries. Dysfunctional relationships may develop that are destructive to the group process and ultimately not in the best interests of individual members.

Decision-Making Groups

The psychiatric nurse often leads decision-making groups that plan activities, develop unit rules, and select learning materials. The nurse who is leading a decision-making group should observe the process for any signs of **groupthink**, the tendency of group members to avoid conflict and adopt a normative pattern of thinking that is often consistent with the ideas of the group leader (Janis, 1972, 1982). Group members form opinions consistent with the group consensus

rather than critically evaluating the situation. Groupthink is more likely to occur if the leader is respected or persuasive. It can also occur if a closed leadership style is used and external threat is present, particularly with time pressure (Cleary et al., 2019). Many catastrophes, such as the *Challenger* explosion and Bay of Pigs invasion, have been attributed to groupthink.

There may be instances in which groupthink can lead to a reasonable decision: for example, a group decides to arrange a going-away party for another patient. In other situations, groupthink may inhibit individual thinking and problem-solving: for example, a team is displaying groupthink if it decides that a patient should lose privileges based on the assumption that the patient is deliberately exhibiting bizarre behaviors. In this case, the team is failing to consider or examine other evidence that suggests the bizarre behavior is really an indication of psychosis. Another commonly occurring instance of groupthink occurs when a decision is made that is recommended by a charismatic leader who is held in high regard by staff members without the evidence to support the approach (Christensen, 2019).

Concept Mastery Alert

Groupthink is the tendency of group members to avoid conflict and adopt a normative pattern of thinking that is often consistent with the ideas of the group leader. Group cohesion is the ability of the group to stick together.

Support Groups

Support groups are usually less intense than psychotherapy groups and focus on helping individuals cope with their illnesses and problems. Implementing support groups is one of the basic functions of the psychiatric nurse. In conducting this type of group, the nurse focuses on helping members cope with situations that are common for other group members. Counseling strategies are used. Leadership of the group requires group management, understanding the impact of the group process, role modeling, awareness, willingness, agreeableness, and openness (Pomeroy et al., 2016). For example, a group of patients with bipolar illness whose illness is stable may discuss at a monthly meeting how to tell other people about the illness or how to cope with a family member who seems insensitive to the illness. Family caregivers of persons with

mental illnesses benefit from the support of the group, as well as additional information about providing care for an ill family member.

Psychotherapy Groups

Psychotherapy groups treat individuals' emotional problems and can be implemented from various theoretic perspectives, including psychoanalytic, behavioral, and cognitive. These groups focus on examining emotions and helping individuals face their life situations. At times, these groups can be extremely intense. Psychotherapy groups provide an opportunity for patients to examine and resolve psychological and interpersonal issues within a safe environment. Mental health specialists who have a minimum of a master's degree and are trained in group psychotherapy lead such groups. Patients can be treated in psychotherapy and still be members of other nursing groups. Communication with the therapists is important for continuity of care.

One of the most respected approaches is Irvin D. Yalom's model of group psychotherapy. According to Yalom and Leszcz (2005), there are 11 primary factors through which therapeutic changes occur ([Table 14.3](#)). In this model, interpersonal relationships are very important because change occurs through a corrective emotional experience within the context of the group. The group is viewed as a social microcosm of the patients' psychosocial environment (Yalom & Leszcz, 2005).

Table 14-3: Yalom's Therapeutic Factors

Therapeutic Factors Definition

Instillation of hope	Hope is required to keep patients in therapy
Universality	Finding out that others have similar problems
Imparting information	Didactic instruction about mental health, mental illness, and so on
Altruism	Learning to give to others
Corrective recapitulation of the primary family group	Reliving and correcting early family conflicts within the group
Development of socializing techniques	Learning basic social skills

Imitative behavior	Assuming some of the behaviors and characteristics of the therapist
Interpersonal learning	Analogue of therapeutic factors in individual therapy, such as insight, working through the transference, and corrective emotional experience
Group cohesiveness	Group members' relationship to therapist and other group members
Catharsis	Open expression of affect to purge or "cleanse" self
Existential factors	Patients' ultimate concerns of existence: death, isolation, freedom, and meaninglessness

Source: Yalom, I., & Leszcz, M. (2005). *The theory and practice of group psychotherapy*. Basic Books.

Self-Help Groups

Self-help groups are led by people who are concerned about coping with a specific problem or life crisis. These groups do not explore psychodynamic issues in depth. Professionals usually do not attend these groups or serve as consultants. Alcoholics Anonymous, Overeaters Anonymous, and One Day at a Time (a grief group) are examples of self-help groups.

Age-Related Groups

Group interventions for specific age groups require attention to the developmental needs of the group members, any physical and mental impairments, social ability, and cognitive level. Children's groups should be structured to accommodate their intellectual and developmental functioning. Groups for older people should be adapted for age-related changes of the members ([Box 14.4](#)).

Box 14.4

Working with Older People in Groups

SELF-ASSESSMENT

Because most group leaders do not have personal experience with the issues faced by older adults, the leaders should sensitize themselves to the positive and negative aspects of aging and the developmental issues facing older adults. Leaders need to be aware of their own negative reactions to aging and how this

might affect their work.

COHORT EXPERIENCES

There is a wide variation in the experiences and history of older adults. Current 80- to 90-year-old adults grew up in the Great Depression of the 1930s, 65- to 80-year-old adults commonly experienced growing up during World War II, and the Baby Boomers (ages 55–65 years) were teenagers or young adults during the political and sexual revolution of the 1960s.

TYPICAL THEMES IN GROUP MEETINGS

- **Continuity with the past:** Older adults enjoy recalling, reliving, and reminiscing about past accomplishments.
- **Understanding the modern world:** They often use groups to understand and adapt to the modern world.
- **Independence:** They worry about becoming dependent. Physical and cognitive impairments are threats to independence. Loss of family members and friends is also a threat. Leaders should be familiar with the grieving processes.
- **Changes in family relationships:** Family relationships, especially with children and grandchildren, are increasingly important as social roles change.
- **Changes in resources and environment:** Living on a fixed income focuses older people on the importance of their disposable income. They are more vulnerable to community and neighborhood changes because of their physical and financial limitations.

GROUP LEADERSHIP

- The pace of group meetings should be slowed.
- Greater emphasis should be placed on using wisdom and experience rather than learning new information.
- The group should be encouraged to use life review strategies such as autobiography and reminiscence.
- Teaching new coping skills should be placed within the context of previous attempts to resolve issues and problems (Toseland & Rizzo, 2004).

COMMON NURSING INTERVENTION GROUPS

Nurses lead groups of varying types that are geared toward a specific content area such as medication management, symptom management, anger management, and self-care skills. In addition, nurses' groups focus on other issues such as stress management, relaxation, and women's issues. A competent leader integrates group leadership, knowledge, and skills with nursing interventions that fit a selected group. Most groups can be adapted to a virtual environment.

Medication Groups

Nurse-led medication groups are common in psychiatric nursing. Not all medication groups are alike, so the nurse must be clear regarding the purpose of each specific medication group (Box 14.5>). A medication group can be used primarily to transmit information about medications, such as action, dosage, and side effects, or it can focus on issues related to medications, such as compliance, management of side effects, and lifestyle adjustments. Many nurses incorporate both perspectives.

Assessing a member's medication knowledge is important before they join the group to determine what the individual would like to learn. People with mental illness may have difficulty remembering new information, so assessment of cognitive abilities is important. Assessing attention span, memory, and problem-solving skills gives valuable information that nurses can use in designing the group. The nurse should determine the members' reading and writing skills to select effective patient education materials.

An ideal group is one in which all members use the same medication. This situation is rare. Usually, the group members are using various medications. The nurse should know which medications each member is taking, but to avoid violating patient confidentiality, the nurse needs to be careful not to divulge that information to other patients. If group members choose, they can share the names of their medications with one another. A small group format works best, and the more interaction, the better. Using a lecture method of teaching is less effective than involving the members in the learning process. The nurse should expose the members to various audio and visual educational materials, including workbooks, videotapes, and handouts. The nurse should ask members to write down information to help them remember and learn through various modes. Evaluation of the learning outcomes begins with the first class. Nurses can develop and give pretests and posttests, which in combination can measure learning outcomes.

BOX 14.5

Medication Group Protocol

PURPOSE: Develop strategies that reinforce a self-medication routine.

DESCRIPTION: The medication group is an open, ongoing group that meets once a week to discuss topics germane to self-administration of medication. Members will not be asked to disclose the names of their medications.

MEMBER SELECTION: The group is open to any person taking medication for a mental illness or emotional problem who would like more information about medication, side effects, and staying on a

regimen. Referrals from mental health providers are encouraged. Each person will meet with the group leader before attending the group to determine if the group will meet the individual's learning needs.

STRUCTURE: The format is a small group, with no more than eight members and one psychiatric nurse group leader facilitating a discussion about the issues. Topics are rotated.

TIME AND LOCATION: 2:00 to 3:00 pm, every Wednesday at the Mental Health Center

COST: No charge for attending

TOPICS

- How Do I Know If My Medications Are Working?
- Side Effect Management: Is It Worth It?
- Hints for Taking Medications Without Missing Doses!
- Health Problems That Medications Affect.
- (Other topics will be developed to meet the needs of group members.)

EVALUATION: Short pretest and posttest for instructor's use only

Symptom Management Groups

Nurses often lead recovery-oriented groups that focus on helping patients deal with a severe and persistent mental illness. Handling hallucinations, being socially appropriate, and staying motivated to complete activities of daily living are a few common topics. In symptom management groups, members also learn when a symptom indicates that relapse is imminent and what to do about it. Within the context of a symptom management group, patients can learn how to avoid relapse.

Anger Management Groups

Anger management is another common topic for a nurse-led group, often in the inpatient setting. The purposes of an anger management group are to discuss the concept of anger, identify antecedents to aggressive behavior, and develop new strategies to deal with anger other than verbal and physical aggression (see [Chapter 20](#)). The treatment team refers individuals with histories of being verbally and physically abusive, usually to family members, to these groups to help them better understand their emotions and behavioral responses. Impulsiveness and emotional lability are problems for many of the group members. Anger management usually includes a discussion of associated stressful situations, events that trigger anger, feelings about the situation, and unmet personal needs.

Self-Care Groups

Another common nurse-led recovery-oriented psychiatric group is a self-care group. People with psychiatric illnesses often have self-care deficits and benefit from the structure that a group provides. These groups are challenging because members usually know how to perform these daily tasks (e.g., bathing, grooming, performing personal hygiene), but their illnesses cause them to lose the motivation to complete them. The leader not only reinforces the basic self-care skills but also, more importantly, helps identify strategies that can motivate the patients and provide structure to their daily lives.

Reminiscence Groups

Reminiscence therapy has been shown to be a valuable intervention for older clients. In this type of group, members are encouraged to remember events from past years. Such a group is easily implemented. Usually, a simple question about an important family event will spark memories. Reminiscence groups are usually associated with patients who have dementia who are having difficulty with recent memory. Reminiscence groups can also be used as an intergenerational intervention with healthy older adults and children. These groups can also reduce symptoms of depression, improve aspects of quality of life, and improve negative attitudes toward old age (Siverová & Bužgová, 2018).

SUMMARY OF KEY POINTS

- The definition of group can vary according to theoretic orientation. A general definition is that a group is two or more people who have at least one common goal or issue. Group dynamics are the interactions within a group that influence the group's development and process.
- Groups can be open, with new members joining at any time, or closed, with members admitted only once. Either small or large groups can be effective, but dynamics change in different size groups.

- Virtual applications are emerging as an important tool in leading groups. The group leader must adapt the technology to the purpose of the group and address issues of confidentiality and privacy when using the internet.
- The process of group development occurs in phases: beginning, middle, and termination. These stages are not fixed but dynamic. The process challenges the leader to guide the group. During the working stage, the group addresses its purpose.
- Leading a group involves many different functions, from obtaining and receiving information to testing and evaluating decisions. The leader should explain the rules of the group at the beginning of the group.
- Verbal communication includes the communication network and group themes. Nonverbal communication is more complex and involves eye contact, body posture, and the mood of the group. Decision-making groups can be victims of groupthink, which can have positive or negative outcomes. Groupthink research is ongoing.
- Seating arrangements can affect group interaction. The fewer physical barriers there are, such as tables, the better the communication. Everyone should be a part of the group, and no one should sit outside of it. In the most interactive groups, members face one another in a circle.
- Leadership skills involve listening; tracking verbal and nonverbal behaviors; and maintaining a neutral, nonjudgmental style.
- Although there are only two formal group roles, leader and member, there are many informal group roles. These roles are usually categorized according to purpose—task functions, maintenance functions, and individual roles. Members who assume task functions encourage the group members to stay focused on the group's task. Those who assume maintenance functions worry more about the group working together than the actual task itself. Individual roles can either enhance or detract from the work of the group.
- The leader should address behaviors that challenge the leadership, group process, or other members to determine whether to intervene. In some

instances, the leader redirects a monopolizing member; at other times, the leader lets the group deal with the behavior. Group conflict occurs in most groups.

- There are many different types of groups. Most groups can be adapted to a virtual platform. Psychiatric nurses lead psychoeducation and support groups. Mental health specialists who are trained to provide intensive therapy lead psychotherapy groups. Consumers lead self-help groups, and professionals assist only as requested. Leading age-related groups requires attention to the developmental, physical, social, and intellectual abilities of the participants. Themes of older adult groups include continuity with the past, understanding the modern world, independence, and changes in family and resources. Group leadership for older adult groups builds on participants' previous experiences and coping abilities in developing new coping skills.
- Medication, symptom management, anger management, and self-care groups are common nurse-led groups focused on specific interventions.

Unfolding Patient Stories: Randy Adams

Part 2

Recall from [Chapter 7](#) Randy Adams, a veteran with symptoms of posttraumatic stress disorder (PTSD) and neurocognitive problems, which manifested after a recent car accident. He has resisted getting care from the Veterans Affairs hospital. How can he benefit from group therapy and be encouraged to attend? What group interventions would the nurse consider for a client with PTSD, who is reexperiencing war events? How can the nurse foster communication and group interactions when he has difficulty expressing his feelings and decreased concentration?

CRITICAL THINKING CHALLENGES

1. Group members are very polite to one another and are superficially discussing topics. You would assess the group as being in which phase? Explain your answer.
2. After three sessions of a support group, two members begin to share their frustration with having a mental illness. The group is moving into which

phase of group development? Explain your answer.

3. Define the roles of the task and maintenance functions in groups. Observe your clinical group and identify classmates who are assuming task functions and maintenance functions.
4. Observe a patient group for at least five sessions. Discuss the seating pattern that emerges. Identify the communication network and the group themes. Then identify the group's norms and standards.
5. Participate in a virtual support or self-help group. Identify the strengths and limitations of using the virtual technology.
6. Discuss the conditions that lead to groupthink. When is groupthink positive? When is groupthink negative? Explain.
7. List at least six behaviors that are important for a group leader, including one for age-related groups. Justify your answers.
8. During the first meeting, one member seems very anxious and tends to monopolize the conversation. Discuss how you would assess the situation and whether you would intervene.
9. At the end of the fourth meeting, one group member angrily accuses another of asking too many questions. The other members look on quietly. How would you assess the situation? Would you intervene? Explain.

Movie Viewing Guides

12 Angry Men: 1998. In this excellent film, a young man stands accused of fatally stabbing his father. A jury of his “peers” is deciding his fate. This jury is portrayed by an excellent cast, including Jack Lemmon, George C. Scott, Tony Danza, and Ossie Davis. At first, the case appears to be “open and shut.” This film depicts an intense struggle to reach a verdict and is an excellent study of group process and group dynamics.

VIEWING POINTS: Identify the leaders in the group. How does leadership change throughout the film? Do you find any evidence of groupthink? How does the group handle conflict?

Family Assessment and Interventions

Mary Ann Boyd

KEYCONCEPTS

- comprehensive family assessment
- family

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Examine the changing family structure and mental health implications.
2. Discuss the impact of mental disorders on a family system.
3. Complete a genogram that depicts the family history, relationships, and mental disorders across at least three generations.
4. Develop a plan for a comprehensive family assessment.
5. Discuss nursing interventions that are useful in caring for families.

KEY TERMS

- Boundaries
- Differentiation of self
- Dysfunctional
- Emotional cutoff
- Extended family
- Family development
- Family life cycle
- Family projection process
- Family structure
- Genogram
- Multigenerational transmission process
- Nuclear family emotional process
- Resilience
- Sibling position
- Subsystems
- Transition times
- Triangles

INTRODUCTION

A *family* is a group of people, connected emotionally, or by blood, or in both ways, that has developed patterns of interaction and relationships. Family members have a shared history and a shared future. Family includes the entire emotional system of three, four, or even five generations held by blood, and legal, emotional, and/or historical ties. Relationships with parents, siblings, and

other family members go through transitions as they move through life. Families are unique in that, unlike all other groups, they incorporate new members only by birth, adoption, or marriage, and members can leave only by divorce or death (McGoldrick et al., 2016).

Key Concept Family is a group of people, connected by emotions, blood, or both, that has developed patterns of interaction and relationships. Family members have a shared history and a shared future (McGoldrick et al., 2016).

The psychiatric nurse interacts with families in various ways. Because of the interpersonal and chronic nature of many mental disorders, psychiatric nurses often have frequent and long-term contact with families. Involvement may range from meeting family members only once or twice to treating the whole family as a patient. Unlike a therapeutic group (see [Chapter 14](#)), the family system has a history and continues to function when the nurse is not there. The family reacts to past, present, and anticipated future relationships within at least a three-generation family system. This chapter explains how to integrate important family concepts into the nursing process when providing nursing care to families experiencing mental health problems.

CHANGING FAMILY STRUCTURE

Although families may be defined differently within various cultures, they all play an important role in our lives and influence who and what we are. Traditionally, families are considered a source of guidance, security, love, and understanding. This is also true for people experiencing mental illnesses and emotional problems. Often the family assumes primary care for the person with mental illness and supports that individual through recovery. For patients, the family unit may provide their only constant support throughout their lives.

Family structure and size influence the strength of a family system. Family structure and size have changed drastically in recent times and so have the functions and roles of family members.

Family Size

Family size in the United States has decreased. In 1790, about one third of all households, including servants, those individuals enslaved, and other people not related to the head, consisted of seven people or more. By 1960, only 1 household in 20 consisted of 7 people or more. The average family household in 2018 was 2.6 people. Married couples make up 47.8% of the households in the United States; almost half of adults today do not live with a spouse (U.S. Census Bureau, 2018).

Contemporary Roles

Men and women's family roles have changed drastically in the past years. Many women work outside the home and many men are involved in parenting. Today, most women, including those who are mothers, work—both in dual-income families and in single-parent families. Women make up 46.9% of the American civilian work force. More than half of the female work force is married, and only 27% of married mothers and 7% of married fathers with children are stay-at-home parents (Livingston, 2018b).

Mobility and Relocation

Families are more mobile and may change residences frequently. Leaving familiar environments and readjusting to new surroundings and lifestyles stress the family system. These moves impose separation from the **extended family**, which traditionally has been a stabilizing force and a much needed support system.

Family Composition

Unmarried Couples

More unmarried couples are cohabitating before or instead of marrying. In the United States, 53% of adults age 18 and older are married, down from 58% in 1995. During that time, the cohabitation rate increased from 3% to 7%. More than half of cohabiters are raising children, including about a third who are

living with a child they share with their partner. There is variation in marriage rates by race and ethnicity. Fifty-seven percent White adults and 63% of Asian adults are married; fewer than half of the Hispanic (48%) and Black adults (33%) are married. The majority of cohabiters have only lived with one partner. Most Americans view cohabitation as acceptable even without marriage plans (Horowitz et al., 2019). (Stepler, 2017)

Single-Parent Families

It is estimated that 50% to 60% of American children will reside at some point in a single-parent home. Almost a quarter of U.S. children live with a single parent, more than any other nation (Kramer, 2019). Single parents are overwhelmingly female. Among single parents, 42% are White and 28% are Black. Single mothers are more than twice as likely to be Black as cohabiting mothers (30% vs. 12%) and approximately four times as likely as married mothers (7% are Black) (Livingston, 2018a).

Stepfamilies

Remarried families or stepfamilies have a unique set of challenges that are not completely understood. More than 50% of U.S. families are remarried or recoupled (U.S. Census Bureau, 2018). Many parents find that stepparenting is much more difficult than parenting a biologic child. The bonding that occurs with biologic children rarely occurs with the stepchildren, whose natural bond is with a parent not living with them. However, the stepparent often assumes a measure of financial and parental responsibility. The care and management of children often become the primary stressor to the marital partners. In addition, the children are faced with multiple sets of parents whose expectations may differ. They may also compete for the children's attention. It is not unusual for second marriages to fail because of the stressors inherent in a remarried family.

Childless Families

Couples can be involuntarily childless because of infertility or voluntarily childless by choice. Approximately 10% to 15% of all couples in the reproductive age are involuntarily childless. As the opportunities for women have increased, many people have chosen not to have children. Research on childlessness is sparse, but it appears lifetime childlessness is associated with long-term illness, poorer midlife physical function for men, and poorer cognition. The studies on depression are mixed in later life (Keenan & Grundy, 2018).

Lesbian, Gay, Bisexual, Transsexual, and Queer or Questioning Families

Among the most stigmatized people are those who are lesbian, gay, bisexual, transsexual, and queer or questioning (LGBTQ). It is estimated that most LGBTQ populations have encountered some form of verbal harassment or violence in their lives. Higher rates of depression, stress, and low self-esteem have been seen in this population than in similar heterosexual groups (Wang et al., 2020). However, these mental health problems may improve as public acceptance increases.

Although, historically, some believed that being LGBTQ was a result of faulty parenting or personal choice, evidence shows that sexual orientation and identity are determined early in life by a combination of factors, including genetic predisposition, biologic development, and environmental events (see Chapter 35). In the past, it was also believed that sexual orientation could be changed through counseling by making a concerted effort to establish new relationships. However, no evidence supports the hypothesis that changes in sexual orientation are possible.

FAMILY MENTAL HEALTH

Families can be viewed as a system often consisting of several generations with multiple health care needs. In a mentally healthy family, members live in harmony among themselves and within society. These families support and nurture their members throughout their lives. However, stress and illnesses can

negatively affect a family's overall mental health. Ideally, families can access health care services in an integrated system where primary health services and mental health care are linked.

Family Dysfunction

A family becomes **dysfunctional** when interactions, decisions, or behaviors interfere with the positive development of the family and its individual members. Most families have periods of dysfunction such as during a crisis or stressful situation when the coping skills are not available. Families usually adapt and regain their mentally healthy balance. A family can be mentally healthy and at the same time have a member who has a mental illness. Conversely, a family can be dysfunctional and have no member with a diagnosable mental illness.

Effects of Mental Illness on Family Functioning

Family members with mental disorders have special needs. Many adults with mental disorders live with their parents well into their 30s and beyond. For these adults with persistent mental illness, the family serves several functions that those without mental illness do not need. Such functions include the following:

- *Providing support.* People with mental illness have difficulty maintaining nonfamilial support networks and may rely exclusively on their families.
- *Providing information.* Families often have complete and continuous information about care and treatment over the years.
- *Monitoring services.* Families observe the progress of their relative and report concerns to those in charge of care.
- *Advocating for services.* Family groups advocate for money for residential care services.

The stigma associated with having a family member with a psychiatric disorder underlies much of the burden and stress the caregivers experience. Families can become socially isolated and financially stressed and lose employment opportunities as they struggle to care for their loved one. Frustration, anxiety, and low self-esteem may result (Yin et al., 2020).

Conflicts can occur between parents and mental health workers who place a

high value on independence. Members of the mental health care system may criticize families for being overly protective when, in reality, the patient with mental illness may face real barriers to independent living. Housing may be unavailable; when available, quality and conditions may be inadequate. The patient may fear leaving home, may be at risk for relapse if they do leave, or may be too comfortable at home to want to leave. When long-term caregivers, usually the parents, die, their adult children with mental illness experience housing disruptions and potentially traumatic transitions. Siblings who have other responsibilities expect to be less involved than their parents in the care and oversight of the mentally ill brother or sister. Few families actually plan for this difficult eventuality (Fekadu et al., 2019).

Nurses must use an objective and rational approach when discussing independence and dependence of those with mental illness who live with aging parents. Family emotions often obscure the underlying issues, but nurses can diffuse such emotions, so that everyone can explore the alternatives comfortably. Although separation must eventually occur, the timing and process vary according to each family's particular situation. Parents may be highly anxious when their adult children first leave home and need reassurance and support.

COMPREHENSIVE FAMILY ASSESSMENT

A comprehensive family assessment is the collection of all relevant data related to family health, psychological well-being, and social functioning to identify problems for which the nurse can generate nursing diagnoses. The assessment consists of a face-to-face interview with family members and can be conducted during several sessions. Nurses conduct a comprehensive family assessment when they care for patients and their families for an extended period. They also use them when a patient's mental health problems are so complex that family support is important for optimal care (Box 15.1).

KEYCONCEPT A comprehensive family assessment is the collection of all relevant data related to family health, psychological well-being, and social functioning to identify problems for which the nurse can generate nursing diagnoses.

Relationship Building

In preparing for a family assessment, nurses must concentrate on developing a relationship with the family. Although necessary when working with any family, relationship development is particularly important for families from ethnic minority cultures; because of the discrimination that they have experienced, they may be less likely to trust those from outside their family or community. Developing a relationship takes time, so the nurse may need to complete the assessment during several meetings rather than just one.

To develop a positive relationship with a family, nurses must establish credibility with the family and address its immediate intervention needs. To establish credibility, the family must see the nurse as knowledgeable and skillful. Possessing culturally competent nursing skills and projecting a professional image are crucial to establishing credibility. With regard to immediate intervention needs, a family that needs shelter or food is not ready to discuss a member's medication regimen until the first needs are met. The nurse will make considerable progress in establishing a relationship with a family when they help members meet their immediate needs.

Genograms

Families possess various structural configurations (e.g., single-parent, multigenerational, same-gender relationships). The nurse can facilitate taking the family history by completing a **genogram**, which is a multigenerational schematic depiction of biologic, legal, and emotional relationships from generation to generation. The nurse can use a genogram as a framework for exploring relationships and patterns of health and illness.

Creating Genograms

A genogram includes the age, dates of marriage and death, and geographic location of each member. Symbols are used in the genogram and are defined in a legend. Squares represent men, and circles represent women; ages are listed inside the squares and circles. Horizontal lines represent marriages with dates;

vertical lines connect parents and children. Genograms can be particularly useful in understanding family history, composition, relationships, and illnesses (Fig. 15.1).

Genograms vary from simple to elaborate. The patient's and family's assessment needs guide the level of detail. In a small family with limited problems, the genogram can be rather general. In a large family with multiple problems, the genogram should reflect these complexities. Thus, depending on the level of detail, nurses collect various data. They can study important events such as marriages, divorces, deaths, and geographic movements. They can include cultural or religious affiliations, education and economic levels, and the nature of the work of each family member. Psychiatric nurses should always include mental disorders and other significant health problems in the genogram.

Analyzing and Using Genograms

For a genogram to be useful in assessment, the nurse needs to analyze the data for family composition, relationship problems, and mental health patterns. Nurses can begin with composition. How large is the family? Where do family members live? A large family whose members live in the same city is more likely to have support than a family in which distance separates members. Of course, this is not always the case. Sometimes even when family members live geographically close, they are emotionally distant from one another.

The nurse should also study the genogram for relationship and illness patterns. For relationship patterns, the nurse may find a history of divorces or family members who do not keep in touch with the rest of the family. The nurse can then explore the significance of these and other relationships. For illness patterns, alcoholism, often seen across several generations, may be prevalent in men on one side of a family. The nurse can then hypothesize that alcoholism is one of the mental health risks for the family and design interventions to reduce the risk. Or the nurse may find via a genogram that members of a family's previous generation were in "state hospitals" or had "nerve problems."

Family Physical and Mental Health

The family assessment includes a thorough picture of physical and mental health

status and how the status affects family functioning. The family with multiple health problems, both physical and mental, must try to manage these problems as well as obtain the many financial and health care resources the family members need.

BOX 15.1

Family Mental Health Assessment

I. Family members present		
Name	Age	Relationship
_____	_____	_____
_____	_____	_____
II. Health status		
Member	Disorder and current treatment	
_____	_____	
_____	_____	
III. Mental health status		
Member	Disorder and current treatment	
_____	_____	
_____	_____	
IV. Impact of mental illness on family function		
Describe the changes that occur in the family as a result of the family member's disorder. _____		

V. Family life cycle		
Describe the family life cycle phase and any transitions that are occurring. _____		

VI. Communication patterns		
Describe the family communication patterns in terms of usual times of communication (morning, dinner, etc.), which family members talk to each other, who communicates the family rules, who carries out discipline. Identify triangulated messages. _____		

VII. Stress and coping		
Identify current family stressful events and family coping mechanisms. _____		

VIII. Problem-solving skills		
Determine who solves problems in the family. Are the problem-solving skills of the family able to manage most family problems? _____		

IX. Family system (from the genogram)		
Family composition _____		
Health and illness patterns _____		
Relationship patterns _____		
Social functioning patterns _____		
Financial and legal status _____		
Formal and informal network _____		
X. Nursing diagnoses		

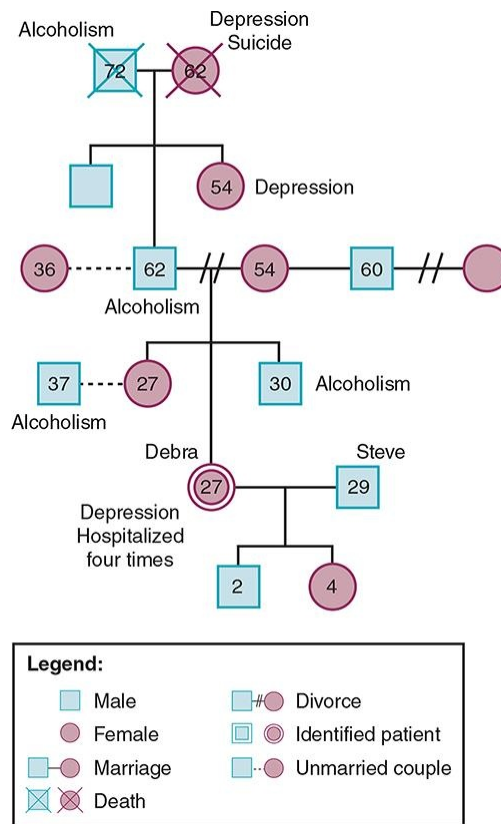

Figure 15-1: Analysis of genogram for Debra. Illness patterns are depression (paternal aunt, grandmother [suicide]) and alcoholism (brother, father, grandfather). Relationship patterns show that the parents are divorced and neither sibling is married.

Physical Health Status

The family health status includes the physical illnesses and disabilities of all members; the nurse can record such information on the genogram and also include the physical illnesses and disabilities of other generations. Illnesses of family members are an indication not only of their physical status but also of the stress currently being placed on the family and its resources. The nurse should pay particular attention to any physical problems that affect family functioning. For example, if a member requires frequent visits to a provider or hospitalizations, the whole family will feel the effects of focusing excessive time and financial resources on that member. The nurse should explore how such situations specifically affect other members.

Mental Health Status

Detecting mental disorders in families may be difficult because these disorders often are hidden or the “family secret.” Very calmly, the nurse should ask family members to identify anyone who has experienced mental illness. The nurse should record the information on the genogram as well as in the narrative. If family members do not know if anyone in the family had or has a mental illness, the nurse should ask if anyone was treated for “nerves” or had a “nervous breakdown.” A good family history of mental illness across multiple generations helps the nurse understand the significance of mental illness in the current generation. If one family member has a serious mental illness, the whole family will be affected. Usually, siblings of the mentally ill member receive less parental attention than the affected member.

Family’s Psychological Domain

Assessment of the family’s psychological domain focuses on the family’s development and life cycle, communication patterns, stress and coping abilities, and problem-solving skills. One aim of the assessment is to understand the relationships within the family. Although family roles and structures are important, the true value of the family is in its relationships, which are irreplaceable. For example, if a parent leaves or dies, another person (e.g., stepparent, grandparent) can assume some parental functions but can never really replace the emotional relationship with the missing parent.

Family Development

Family development is a broad term that refers to all the processes connected with the growth of a family, including changes associated with work, geographic location, migration, acculturation, and serious illness. In optimal family development, family members are relatively differentiated (capable of autonomous functioning) from one another, anxiety is low, and the parents have good emotional relationships with their own families of origin.

Family Life Cycles

The concept of **family life cycle** refers to a system evolving through phases based on significant events related to the arrival and departure of members, such as birth or adoption, child-rearing, departure of children from home, occupational retirement, and death. Identifying the family life cycle is helpful in assessing family relationships, roles, and stresses. The family life cycle is a process of expansion, contraction, and realignment of relationship systems to support the entry, exit, and development of family members (Table 15.1) (McGoldrick et al., 2016). A family's life cycle is conceptualized in terms of phases throughout the years. To move from one phase to the next, the family system undergoes changes. Structural and potential structural changes within phases can usually be handled by rearranging the family system (first-order changes), but transition from one phase to the next requires changes in the system itself (second-order changes). An example of a first-order change is when all the children are finally in school and the stay-at-home parent returns to work. The system is rearranged, but the structure remains the same. In second-order changes, the family structure does change, such as when a member moves away from the family home to live independently.

Table 15-1: Phases of the Family Life Cycle

Emotional Process of Family Life Transition: Key Cycle Phase Prerequisite Attitudes		Changes in the System to Proceed Developmentally
Emerging young adults	Accepting emotional and financial responsibility for self	<ol style="list-style-type: none">1. Differentiation of self in relation to family of origin2. Development of intimate peer relationships3. Establishment of self in respect to work and financial independence4. Establishment of self in community and larger society5. Establishment of one's worldview, spirituality, religion, and relationship to nature6. Parents shifting to consultative role in young adult's relationships

Couple formation: The joining of families	Commitment to new system	<ol style="list-style-type: none"> 1. Formation of couple systems 2. Expansion of family boundaries to include new partner and extended family 3. Realignment of relationships with extended family, friends, and larger community to include new partners
Families with young children	Accepting new members into the system	<ol style="list-style-type: none"> 1. Adjustment of couple system to make space for children 2. Collaboration in child-rearing, financial, and housekeeping tasks 3. Realignment of relationships with extended family to include parenting and grandparenting roles 4. Realignment of relationships with community and larger social system to include new family structure and relationships
Families with adolescents	Increasing flexibility of family boundaries to permit children's independence and grandparents' frailties	<ol style="list-style-type: none"> 1. Shift of parent-child relationships to permit adolescent to have more independent activities and relationships and to move more flexibility into and out of system 2. Refocus on midlife couple and career issues 3. Begin shift toward caring for older generation
Launching children and moving on into midlife	Accepting a multitude of exits from and entries into the system	<ol style="list-style-type: none"> 1. Renegotiation of couple system as a dyad 2. Development of adult-to-adult relationships between parents and grown children 3. Realignment of relationships to include in-laws and grandchildren 4. Realignment of relationships with community and larger social system to include new structure and constellation of family relationships 5. Exploration of new interests or career given the freedom from child care responsibilities 6. Dealing with care needs, disabilities, and death of parents (grandparents)
Families in late middle age	Accepting the shifting generational roles	<ol style="list-style-type: none"> 1. Maintaining or modifying own and/or couple and social functioning and interests in face of physiologic decline: exploration of new familial and social role options

Families nearing the end of life Accepting the realities of limitations and death and the completion of one cycle of life

2. Supporting more central role of middle generations
3. Making room in the system for the wisdom and experience of elders
4. Supporting the older generation without overfunctioning for them

1. Dealing with loss of spouse, siblings, and other peer
2. Making preparations for death and legacy
3. Managing reversed roles in caretaking between middle and older generations
4. Realignment of relationships with larger community and social system to acknowledge changing life cycle relationships

McGoldrick, M., Garcia Preto, N., & Carter, B. (2016). Overview: The life cycle in its changing context: Individual, family and social perspectives. In M. McGoldrick, N. Garcia Preto, & B. Carter (Eds.). *The expanding family life cycle: Individual, family, and social perspectives* (5th ed., pp. 24–25). © 2016. Reprinted by permission of Pearson Education, Inc.

NCLEXNOTE Apply family life cycle phases to a specific family with a member who has a psychiatric disorder. Identify the emotional transitions and the required family changes.

The nurse should not view a family model as “the normal” life cycle because a family’s system is always evolving. As second marriages, career changes in midlife, and other life events occur with increasing frequency, this traditional model is being modified and redesigned to address contemporary structural and role changes. This model also may not fit many cultural groups. Variations of the family life cycle are presented for the divorced and remarried family ([Table 15.2](#)).

Transition times are the addition, subtraction, or change in status of family members. During transitions, family stresses are more likely to cause symptoms or dysfunction. Significant family events, such as the death of a member or the introduction of a new member, also affect the family’s ability to function. During transitions, families may seek help from the mental health system.

Cultural Variations

In caring for families from diverse cultures, the nurse should examine whether the underlying assumptions and frameworks of the dominant life cycle models apply. Even the concept of “family” varies among cultures. For example, the

dominant White middle-class culture's definition of family refers to the intact nuclear family. Many children grow up with parents from separate cultures where they experience differences in daily living. For Italian Americans, the entire extended network of aunts, uncles, cousins, and grandparents may be involved in family decision-making and share holidays and life cycle transitions. For African Americans, the family may include a broad network of kin and community that includes long-time friends who are considered family members (McGoldrick et al., 2016).

Cultural groups also differ in the importance they give to certain life cycle transitions. For example, Irish American families may emphasize the wake, viewing death as an important life cycle transition. African American families may emphasize funerals, going to considerable expense and delaying services until all family members arrive. Italian American and Polish American families may place great emphasis on weddings (McGoldrick et al., 2016).

The life cycle of Mexican immigrant families can be examined in the context of *familismo* (a value of close connection between immediate and extended family members), parental authority, and extended family. The impact of living in a different country, learning a different language, and lack of extended family may create family conflict as they adjust to a different cultural environment. Their children are faced with academic expectations that need parental involvement and support. Family emotional climate increases as both parents share parenting responsibilities (Valdez & Martinez, 2019).

Work and Family Conflict

While work can provide the economic security of a family, it can also cause stress. Parents are often torn between responsibilities of work and home. Conflict between two expectations can lead to additional family stress and poorer mental health (see [Box 15.2](#)).

Families in Poverty

Prior to the coronavirus disease 2019 pandemic, 10.5% of the U.S. population lived below the poverty rate. During the pandemic, the poverty rate in the United States reached 17.5% (Boghani, 2020). As the impact of the pandemic is beginning to subside, the poverty rate is expected to decrease. A disproportionate number of children from minority groups live in poverty. LGBTQ people have a

poverty rate of 21.6%, much higher than others (Badgett et al., 2019).

The family life cycle of those living in poverty may vary from those with adequate financial means. People living in poverty struggle to make ends meet, and family members may face difficulties in meeting their own or other members' basic developmental needs. To experience poverty does not mean that a family is automatically dysfunctional. But poverty is an important factor that can force even the healthiest families to crumble.

Communication Patterns

Family communication patterns develop over a lifetime and are important information during an assessment. Some family members communicate more openly and honestly than others. In addition, family subgroups develop from communication patterns. Just as in any assessment interview, the nurse should observe the verbal and nonverbal communication of the family members. Who sits next to each other? Who talks to whom? Who answers most questions? Who volunteers information? Who changes the subject? Which subjects seem acceptable to discuss? Which topics are not discussed? Can spouses be intimate with each other? Are any family secrets revealed? Does the nonverbal communication match the verbal communication? Nurses can use all of this information to help identify family problems and communication issues.

Table 15-2: Family Life Cycle for the Divorcing and Remarrying Families

Phase and Task	Emotional Process	Developmental Issues
Divorce		
Decision to divorce	Acceptance of inability to resolve marital problems sufficiently to continue relationship	Acceptance of one's own part in the failure of the marriage
Planning the breakup of the system	Supporting viable arrangements for all parts of the system	<ol style="list-style-type: none">1. Working cooperatively on problems of custody, visitation, and finances2. Dealing with extended

		family about the divorce
Separation	<ol style="list-style-type: none"> 1. Willingness to continue cooperative coparental relationship and joint financial support of children 2. Working on resolution of attachment to spouse 	<ol style="list-style-type: none"> 1. Mourning loss of intact family 2. Restructuring marital and parent–child relationships and finances; adaptation to living apart 3. Realignment of relationships with extended family; staying connected with spouse’s extended family
Divorce	Working on emotional divorce: overcoming hurt, anger, guilt, and so on	<ol style="list-style-type: none"> 1. Mourning loss of intact family; giving up fantasies of reunion 2. Retrieving hopes, dreams, expectations from the marriage 3. Staying connected with extended families

Postdivorce Family

Single parent (custodial household or primary residence)	Willingness to maintain financial responsibilities, continue parental contact with ex-spouse, and support contact of children with ex-spouse and their family	<ol style="list-style-type: none"> 1. Making flexible visitation arrangements with ex-spouse and family 2. Rebuilding own financial resources 3. Rebuilding own social network
Single parent (noncustodial)	Willingness to maintain financial responsibilities and parental contact with ex-spouse and to support custodial parent’s relationship with children	<ol style="list-style-type: none"> 1. Finding ways to continue effective parenting 2. Maintaining financial responsibilities to ex-spouse and children 3. Rebuilding own social network

Remarriage

Entering new relationship	Recovery from loss of first marriage (adequate “emotional divorce”)	Recommitment to marriage and to forming a family with readiness to deal with the complexity and ambiguity
---------------------------	---	---

Conceptualizing and planning new marriage and family	<p>Accepting one's own fears and those of new spouse and children about forming a new family</p> <p>Accepting the need for time and patience for adjustment to complexity and ambiguity of the following:</p> <ol style="list-style-type: none"> 1. Multiple new roles 2. Boundaries: space, time, membership, and authority 3. Affective issues: guilt, loyalty conflicts, desire for mutuality, unresolvable past hurts 	<ol style="list-style-type: none"> 1. Working on openness in the new relationships to avoid pseudomutuality 2. Planning for maintenance of cooperative financial and coparental relationships with ex-spouses 3. Planning to help children deal with fears, loyalty conflicts, and membership in two systems 4. Realignment of relationships with extended family to include new spouse and children 5. Plan maintenance of connections for children with extended family of ex-spouses
Remarriage and reconstruction of family	<ol style="list-style-type: none"> 1. Resolution of attachment to previous spouse and ideal of "intact" family 2. Acceptance of different models of family with permeable boundaries 	<ol style="list-style-type: none"> 1. Restructuring family boundaries to allow for inclusion of new spouse—stepparent 2. Realignment of relationships and financial arrangements to permit interweaving of several systems 3. Making room for relationships of all children with all parents, grandparents, and other extended family 4. Sharing memories and histories to enhance stepfamily integration
Renegotiation of remarried family at all future life cycle transitions	<p>Accepting evolving relationships of transformed remarried family</p>	<ol style="list-style-type: none"> 1. Changes as each child graduates, marries, dies, or becomes ill 2. Changes as each spouse forms new couple relationship, remarries, moves, becomes ill, or dies

Parenting Stress

Cherry, K. E., Gerstein, E. D., & Ciciolla, L. (2019). Parenting stress and children's behavior: Transactional models during Early Head Start. *Journal of Family Psychology: JFP : Journal of the Division of Family Psychology of the American Psychological Association (Division 43)*, 33(8), 916–926. <https://doi.org/10.1037/fam0000574>

THE QUESTION: Is parental stress linked to childhood behavior?

METHODS: Data were taken from the Early Head Start Family and Child Experiences Study, where 835 parent–child dyads were assessed at 1, 2, and 3 years. Parenting stress and behavior problems were measured at all three time points, while family conflict and observed parental supportiveness were measured at ages 2 and 3.

FINDINGS: Results indicated that parenting stress and children's behavior problems were relatively stable over time and influenced each other. Family conflict escalated children's behavior problems at age 1 and parenting stress at age 3, while parental supportiveness served a protective role in parent–child relationship.

IMPLICATIONS FOR NURSING: Early prevention programs should focus on both children's behavior and parenting stress in the first year and work to reduce family conflict and increase parental supportiveness.

Nurses should also assess the family for its daily communication patterns. Identifying which family members confide in one another is a place to start examining ongoing communication. Other areas include how often children talk with parents, which child talks to the parents most, and who is most likely to discipline the children. Another question considers whether family members can express positive and negative feelings. In determining how open or closed the family is, the nurse explores the type of information the family shares with nonfamily members. For example, whereas one family may tell others about a member's mental illness, another family may not discuss any illnesses with those outside the family.

Stress and Coping Abilities

One of the most important assessment tasks is to determine how family members deal with major and minor stressful events and their available coping skills. Some families seem able to cope with overwhelming stresses, such as the death

of a member, major illness, or severe conflict, but other families seem to fall apart over relatively minor events. Some family caregivers of persons with mental illness have **resilience**, the ability to recover or adjust to challenges over time. For some families, they not only survive the day-to-day stresses of caring for a family member with a serious mental health problem but also seem to grow stronger and healthier. It is important for the nurse to listen to which situation a family appraises as stressful and help the family identify usual coping responses. The nurse can then evaluate these responses. On the other hand, if the family's responses are maladaptive (e.g., substance abuse, physical abuse), the nurse will discuss the need to develop coping skills that lead to family well-being (see [Chapter 19](#)).

NCLEXNOTE Identifying stressful events and coping mechanisms should be a priority in a family assessment.

Problem-Solving Skills

Nurses assess family's problem-solving skills by focusing on the more recent problems the family has experienced and determining the process that members used to solve them. For example, a child is sick at school and needs to go home. Does the mother, father, grandparent, or babysitter receive the call from the school? Who then cares for the child? Underlying the ability to solve problems is the decision-making process. Who makes and implements decisions? How does the family handle conflict? All of these data provide information regarding the family's problem-solving abilities. After these abilities are identified, the nurse can build on these strengths in helping families deal with additional problems.

Family Social Domain

An assessment of the family's social domain provides important data about the operation of the family as a system and its interaction within its environment. Areas of concern include the system itself, social and financial status, and formal and informal support networks.

Family Systems

Just as any group can be viewed as a system, a family can be understood as a system with interdependent members. Family system theories view the family as an open system whose members interact with their environment as well as among themselves. One family member's change in thoughts or behavior can cause a ripple effect and change in everyone else's. For example, a mother who decides not to pick up her children's clothing from their bedroom floors anymore forces the children to deal with the cluttered rooms and dirty clothes in a different way than before.

One common scenario in the mental health field is the effect of a patient's improvement on the family. With new medications and treatment, patients are more likely to be able to live independently, and this subsequently changes the responsibilities and activities of family caregivers. Although on the surface members may seem relieved that their caregiving burden is lifted, in reality, they must adjust their time and energies to fill the remaining void. This transition may not be easy because it is often less stressful to maintain familiar activities than to venture into uncharted territory. Families may seem as though they want to keep an ill member dependent, but in reality, they are struggling with the change in their family system.

Several system models are used in caring for families: the Wright Leahey Calgary model (Shajani & Snell, 2019); Bowen family system (1975, 1976); and Minuchin, Lee, and Simon's (1996) structural family system.

Calgary Family Model

Lorraine M. Wright and Maureen Leahey developed the Calgary Family Assessment Model and the Calgary Family Intervention Model. These nursing models are based on systems, cybernetics, and communication and change theories (Shajani & Snell, 2019). Families seek help when they have family health and illness problems, difficulties, and suffering. These two models are multidimensional frameworks that conceptualize the family into structural, developmental, and functional categories. Each assessment category contains several subcategories. Structure is further categorized into internal (e.g., family, gender, sexual orientation), external (i.e., extended family and larger systems), and context (i.e., ethnicity, race, social class, religion, spirituality, environment). Family developmental assessment is organized according to stages, tasks, and

attachments. Functional assessment areas include instrumental (e.g., activities of daily living) and expressive (i.e., communication, problem-solving roles, beliefs).

The Calgary Family Assessment Model and Calgary Family Intervention Model are built around four stages: engagement, assessment, intervention, and termination. The *engagement* stage is the initial stage in which the family is greeted and made comfortable. In the *assessment* stage, problems are identified and relationships among family members and health providers develop. During this stage, the nurse opens space for the family members to tell their story. The *intervention* stage is the core of the clinical work and involves providing a context in which the family can make changes (see Intervention section in this chapter). The *termination* phase refers to the process of ending the therapeutic relationship (Shajani & Snell, 2019).

Family Systems Therapy Model

Murray Bowen (1913–1990) recognized the power of a system and believed that there is a balance between the family system and the individual. Bowen developed several concepts that professionals often use today when working with families (Bowen, 1975, 1976; Kerr, 2019).

Differentiation of self involves two processes: intrapsychic and interpersonal. Intrapsychic differentiation means separating thinking from feeling: a differentiated individual can distinguish between thoughts and feelings and can consequently think through behavior. For example, a person who has experienced intrapsychic differentiation, even though angry, will think through the underlying issue before acting. However, the feeling of the moment will drive the behavior of an undifferentiated individual. Interpersonal differentiation is the process of freeing oneself from the family's emotional chaos. That is, the individual can recognize the family turmoil but avoid reentering arguments and issues. For Bowen, the individual must resolve attachment to this chaos before they can differentiate into a mature, healthy personality.

Triangles: According to Bowen, the triangle is a three-person system and the smallest stable unit in human relations. Cycles of closeness and distance characterize a two-person relationship. When anxiety is high during periods of distance, one party “triangulates” a third person or thing into the relationship. For example, two partners may have a stable relationship when anxiety is low. When anxiety and tension rise, one partner may be so uncomfortable they

confide in a friend instead of the other partner. In these cases, triangulating reduces the tension but freezes the conflict in place. In families, triangulating occurs when a husband and wife diffuse tension by focusing on the children. To maintain the status quo and avoid the conflict, which tends to produce symptoms in the child (e.g., bed wetting, fear of school), one of the parents develops an overly intense relationship with one of the children.

Family projection process: Through this process, the triangulated member becomes the center of the family conflicts; that is, the family projects its conflicts onto the child or other triangulated person. Projection is an anxious, enmeshed concern. For example, a husband and wife are having difficulty deciding how to spend money. One of their children is having difficulty with interpersonal relationships in school. Instead of the parents resolving their differences over money, one parent focuses on the child's needs and becomes intensely involved in the child's issues. The other parent then relates coolly and distantly to the involved parent.

Nuclear family emotional process: This concept describes patterns of emotional functioning in a family in a single generation. This emotional distance is a patterned reaction in daily interactions with the spouse.

Multigenerational transmission process: Bowen believed that one generation transfers its emotional processes to the next generation. Certain basic patterns among parents and children are replicas of those of past generations, and generations to follow will repeat them. The child who is the most involved with the family is least able to differentiate from their family of origin and passes on conflicts from one generation to another. For example, a spouse may stay emotionally distant from his partner just as his father was with his mother.

Sibling position: Children develop fixed personality characteristics based on their sibling position in their families. For example, a first-born child may have more confidence and be more outgoing than the second-born child, who has grown up in the older child's shadow. Conversely, the second-born child may be more inclined to identify with the oppressed and be more open to other experiences than the first-born child. These attitudinal and behavioral patterns become fixed parts of both children's personalities. Knowledge of these general personality characteristics is helpful in predicting the family's emotional processes and patterns. These theoretical ideas of Bowen have not been supported by research, but the more general principle that a child's position in the family origin affects the child has significant empirical support (Bleske-Rechek & Kelley, 2014; Green & Griffiths, 2014).

Emotional cutoff: If a member cannot differentiate from their family, that member may just flee from the family, either by moving away or avoiding personal subjects of conversation. Yet a brief visit from parents can render these individuals helpless.

In using the family systems therapy model, the nurse can observe family interactions to determine how differentiated family members are from one another. Are members autonomous in thinking and feeling? Do triangulated relationships develop during periods of stress and tension? Are family members interacting in the same manner as their parents or grandparents? How do the personalities of older siblings compare with those of younger siblings? Who lives close to one another? Does any family member live in another city? The Bowen model can provide a way of assessing the system of family relationships (Yektatalab et al., 2017).

Family Structure Model

Salvador Minuchin (1921–2017) emphasizes the importance of family structure. In their model, the family consists of three essential components: structure, subsystems, and boundaries.

Family structure is the organized pattern in which family members interact. As two adult partners come together to form a family, they develop the quantity of their interactions or how much time they spend interacting. For example, a newly married couple may establish their evening interaction pattern by talking to each other during dinner but not while watching television. The quality of the interactions also becomes patterned. Whereas some topics are appropriate for conversation during their evening walk (e.g., reciting daily events), controversial or emotionally provocative topics are relegated to other times and places (Minuchin et al., 1996).

Family rules are important influences on interaction patterns. For example, “family problems stay in the family” is a common rule. Both the number of people in the family and its development also influence the interaction pattern. For instance, the interaction between a single mother and her children changes when she remarries and introduces a stepfather. Over time, families repeat interactions, which develop into enduring patterns. For example, if a mother tells her son to straighten his room and the son refuses until his father yells at him, the family has initiated an interactional pattern. If this pattern continues, the child will come to see the father as the disciplinarian and the mother as

incompetent. However, the mother will be more affectionate to her son, and the father will remain the disciplinarian on the “outside.”

Subsystems develop when family members join together for various activities or functions. Minuchin et al. (1996) view each member, as well as dyads and other larger groups that form, as a subsystem. Obvious groups are parents and children. Sometimes, there are “boy” and “girl” systems. Such systems become obvious in an assessment when family members talk about “the boys going fishing with dad” and “the girls going shopping with mother.” Family members belong to several different subgroups. A mother may also be a wife, sister, and daughter. Sometimes, these roles can conflict. It may be acceptable for a woman to be very firm as a disciplinarian in her role as mother. However, in her sister, wife, or daughter role, similar behavior would provoke anger and resentment.

Boundaries are invisible barriers with varying permeabilities that surround each subsystem. They regulate the amount of contact a person has with others and protect the autonomy of the family and its subsystems. If family members do not take telephone calls at dinner, they are protecting themselves from outside intrusion. When parents do not allow children to interrupt them, they are establishing a boundary between themselves and their children. According to Minuchin et al. (1996), the spouse subsystem must have a boundary that separates it from parents, children, and the outside world. A clear boundary between parent and child enables children to interact with their parents but excludes them from the spouse subsystem.

Boundaries vary from rigid to diffuse. If boundaries are too rigid and permit little contact from outside subsystems, disengagement results, and disengaged individuals are relatively isolated. On the other hand, rigid boundaries permit independence, growth, and mastery within the subsystem, particularly if parents do not hover over their children, telling them what to do or fighting their battles for themselves. Enmeshed subsystems result when boundaries are diffuse. That is, when boundaries are too relaxed, parents may become too involved with their children, and the children learn to rely on the parents to make decisions, resulting in decreased independence. According to Minuchin et al. (1996), if children see their parents as friends and treat them as they would treat their peers, then enmeshment exists.

Autonomy and interdependence are key concepts, important both to individual growth and family system maintenance. Relationship patterns are maintained by universal rules governing family organization (especially power hierarchy) and mutual behavioral expectations. In the well-functioning family, boundaries are

clear, and a hierarchy exists with a strong parental subsystem. Problems result when there is a malfunctioning of the hierarchical arrangement or boundaries or a maladaptive reaction to changing developmental or environmental requirements. Minuchin et al. (1996) believe in clear, flexible boundaries by which all family members can live comfortably.

In the family structural theory, what distinguishes normal families is not the absence of problems but a functional family structure to handle them. Husbands and wives must learn to adjust to each other, rear their children, deal with their own parents, cope with their jobs, and fit into their communities. The types of struggles change with developmental stages and situational crises. The psychiatric nurse assesses the family structure and the presence of subsystems or boundaries. The nurse uses these data to determine how the subsystems and boundaries affect the family's functioning. Helping family members change a subsystem, such as including younger and older children together in family activities, may improve family functioning.

Social and Financial Status

Social status is often linked directly to financial status. The nurse should assess the occupations of the family members. Who works? Who is primarily responsible for the family's financial support? Families of low social status are more likely to have limited financial resources, which can place additional stresses on the family. Cultural expectations and beliefs about acceptable behaviors may cause additional stress when in conflict with beliefs of caregivers. Nurses can use information regarding the family's financial status to determine whether to refer the family to social services.

Formal and Informal Support Networks

Both formal and informal networks are important in providing support to individuals and families and should be identified in the assessment. These networks are the link among the individual, families, and the community. Assessing the extent of formal support (e.g., hospitals, agencies) and informal support (e.g., extended family, friends, and neighbors) gives a clearer picture of

the availability of support. In assessing formal support, the nurse should ask about the family's involvement with government institutions and self-help groups such as Alcoholics Anonymous. Assessing the informal network is particularly important in cultural groups with extended family networks or close friends because these individuals can be major sources of support to patients. If the nurse does not ask about the informal network, these important people may be missed. Nurses can inquire whether family members volunteer at schools, local hospitals, or nursing homes. They can also ask whether the family attends religious services or activities.

FAMILY INTERVENTIONS

Family interventions focus on supporting the integrity and functioning of the family as defined by its members. Although family therapy is reserved for mental health specialists, the generalist psychiatric mental health nurse can implement several interventions, such as counseling, promotion of self-care activities, supportive therapy, education and health teaching, and the use of genograms.

In implementing any family intervention, flexibility is essential, particularly when working with culturally diverse groups. The nurse creates the context for change by making sure the interventions are possible for the family (Shajani & Snell, 2019). For example, weekly appointments may be ideal but impossible for a busy family. To implement successful, culturally competent family interventions, nurses need to be open to modifying the structure and format of the sessions. Longer sessions are often useful, especially when a translator or interpreter is used. Nurses also need to respect and work with the changing family composition of family and nonfamily participants (e.g., extended family members, intimate partners, friends and neighbors, community helpers) in sessions. Because of the stigma that some cultural groups associate with seeking help, nurses may need to hold intervention sessions in community settings (e.g., churches and schools) or at the family's home. If adequate progress is made, it is time to decrease the frequency of sessions and move toward termination. Families may move toward termination if they recognize that improvement has been made (Shajani & Snell, 2019).

Counseling

Nurses often use counseling when working with families because it is a short-term problem-solving approach that addresses current issues. The nurse should avoid taking sides by forming an alliance with one family member or subgroup (Shajani & Snell, 2019). If the assessment reveals complex, long-standing relationship problems, the nurse needs to refer the family to a family therapist. If the family is struggling with psychiatric problems of one or more family members or the family system is in a life cycle transition, the nurse should use short-term counseling. Instead of giving advice, the counseling sessions should focus on specific issues or problems using sound group process theory. Usually, a problem-solving approach works well after an issue has been identified (see [Chapter 19](#)).

Promoting Self-Care Activities

Families often need support in changing behaviors that promote self-care activities. For example, families may inadvertently reinforce a family member's dependency out of fear of the patient being taken advantage of in work or social situations. A nurse can help the family explore how to meet the patient's need for work and social activity and at the same time help alleviate the family's fears.

Caregiver distress or role strain can occur in families that are responsible for the care of members with long-term illness. Family interventions can help families deal with the burden of caring for members with psychiatric disorders. Family intervention may decrease the frequency of relapse (in persons with schizophrenia) and encourage compliance with medication (Okpokoro et al., 2014).

Supporting Family Functioning and Resilience

Supporting family functioning involves various nursing approaches. In meeting with the family, the nurse should identify and acknowledge its values. In developing a trusting relationship with the family, the nurse should confirm that all members have a sense of self and self-worth. Encouraging positive thinking and participating in support groups will contribute to the family's well-being.

Supporting family subsystems (e.g., encouraging the children to play while meeting with the spouses) reinforces family boundaries. Based on assessment of the family system's operation and communication patterns, the nurse can reinforce open, honest communication.

In communicating with the family, the nurse needs to observe boundaries constantly and avoid becoming triangulated into family issues. An objective, empathic leadership style can set the tone for the family sessions.

Providing Education and Health Teaching

One of the most important family interventions is education and health teaching, particularly in families with mental illness. Families have a central role in the treatment of mental illnesses. Members need to learn about mental disorders, medications, actions, side effects, and overall treatment approaches and outcomes. For example, families are often reluctant to have members take psychiatric medications because they believe the medications will “drug” the patient or become addictive. The family's beliefs about mental illnesses and treatment can affect whether patients will be able to manage their illness.

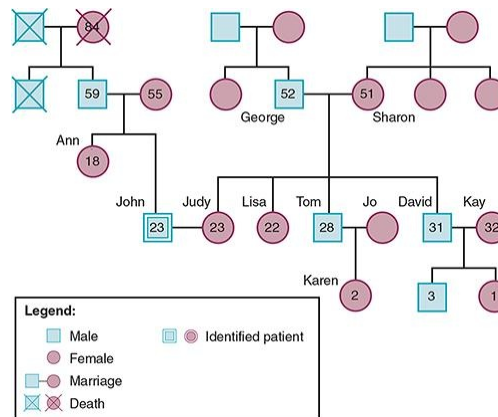

Using Genograms

Genograms not only are useful in assessment but also can be used as intervention strategies. Nurses can use genograms to help family members understand current feelings and emotions as well as the family's evolution over several generations. Genograms allow the family to examine relationships from a factual, objective perspective. Often, family members gain new insights and can begin to understand their problems within the context of their family system. For example, families may begin to view depression in an adolescent daughter with new seriousness when they see it as part of a pattern of several generations of women who have struggled with depression. A husband, raised as an only child in a small Midwestern town, may better understand his feelings of being overwhelmed after comparing his family structure with that of his wife, who comes from a large family of several generations living together in the urban Northeast ([Box 15.3](#)).

Box 15.3

John and Judy Jones

John and Judy Jones were married 3 years ago after their graduation from a small liberal arts college in the Midwest. Judy's career choice required that she live on the East Coast where she should be near her large family. John willingly moved with her and quickly found a satisfying position. After about 6 months of marriage, John became extremely irritable and depressed. He kept saying that his life was not his own. Judy was very concerned but could not understand his feelings of being overwhelmed. His job was going well, and they had a very busy social life, mostly revolving around her family, whom John loved. They decided to seek counseling and completed the following genogram:

After looking at the genogram, both John and Judy began to realize that part of John's discomfort had to do with the number of family members who were involved in their lives. Judy and John began to redefine their social life, allowing more time with friends and each other.

SUMMARY OF KEY POINTS

- The family is an important societal unit that often is responsible for the care and coordination of treatment of members with mental disorders. The family structure, size, and roles are rapidly changing. Traditional health care services will have to adapt to meet the mental health care needs of these families.
- A family is a group of people who are connected emotionally, by blood, or in both ways that has developed patterns of interactions and relationships. Families come in various compositions, including nuclear, extended, multigenerational, single-parent, and same-gender families. Cultural values

and beliefs define family composition and roles.

- Nurses complete a comprehensive family assessment when they care for families for extended periods or if a patient has complex mental health problems.
- In building relationships with families, nurses must establish credibility and competence with the family. Unless the nurse addresses the family's immediate needs first, the family will have difficulty engaging in the challenges of caring for someone with a mental disorder.
- The genogram is an assessment and intervention tool that is useful in understanding health problems, relationship issues, and social functioning across several generations.
- In assessing the family, the nurse determines physical and mental health status and their effects on family functioning.
- Family members are often reluctant to discuss the mental disorders of family members because of the stigma associated with mental illness. In many instances, family members do not know whether mental illnesses were present in other generations.
- The family psychological assessment focuses on family development, the family life cycle, communication patterns, stress and coping abilities, and problem-solving skills. One assessment aim is to begin to understand family interpersonal relationships.
- The family life cycle is a process of expansion, contraction, and realignment of the relationship systems to support the entry, exit, and development of family members in a functional way. The nurse should determine whether a family fits any of the life cycle models. Families living in poverty may have a condensed life cycle.
- In assessing the family social domain, the nurse compiles data about the system itself, social and financial status, and formal and informal support networks.
- The family system model proposes that a balance should exist between the

family system and the individual. A person not only needs family connection but also needs to be differentiated as an individual. Important concepts include triangles, family projection process, nuclear family emotional process, multigenerational transmission, sibling position, and emotional cutoff.

- The family structure model explains patterns of family interaction. Subsystems develop that also influence interaction patterns. Boundaries can vary from rigid to relaxed. The rigidity of the boundaries affects family functioning.
- Family interventions focus on supporting the family's integrity and functioning as defined by its members. Family nursing interventions include counseling, promotion of self-care activities, supportive therapy, education and health teaching, and the use of genograms. Mental health specialists, including advanced practice nurses, conduct family therapy.
- Education of the family is one of the most useful interventions. Teaching the family about mental disorders, life cycles, family systems, and family interactions can help the family develop a new understanding of family functioning and the effects of mental disorders on the family.

CRITICAL THINKING CHALLENGES

1. How can a group of people who are unrelated by blood consider themselves a family?
2. Interview a family with a member who has a mental illness and identify who provides support to the individual and family during acute episodes of illness.
3. Interview someone from another culture regarding family beliefs about mental illness. Compare them with your own.
4. Develop a genogram for your family. Analyze the genogram for its pattern of health problems, relationship issues, and social functioning.
5. A female patient, divorced with two small children, reports that she is considering getting married again to a man whom she met 6 months ago. She asks for help in considering the advantages and disadvantages of remarriage.

Using the remarried family formulations life cycle model, develop a plan for structuring the counseling session.

5. Define Minuchin et al.'s term *family structure* and use that definition in observing your own family and its interaction.
7. Discuss what happens to a family that has rigid boundaries.
3. A family is finding it difficult to provide transportation to a support group for an adult member with mental illness. The family is committed to his treatment but is also experiencing severe financial stress because of another family illness. Using a problem-solving approach, outline a plan for helping the family explore solutions to the transportation problem.

Movie Viewing Guides

Call Me by Your Name: 2017. In 1983, the Perlman family invite a 24-year-old, American graduate student, Oliver, to spend 6 weeks with them over the summer to help Professor Perlman with his work. The location is northern Italy in a 17th century villa, where the Perlman family spend their summers and Hannukkah. Oliver associates with the Perlman family 17-year-old son Elio and Elio's friends. During the course of 6 weeks, Oliver and Elio realize their strong attraction to each other and develop a clandestine relationship.

VIEWING POINTS: Observe your feelings as you watch this movie. Identify the cultural mores that prevent Oliver and Elio from being open about their relationship.

My Big Fat Greek Wedding: 2002. This movie is about Fotoula "Toula" Portokalos, a Greek-American woman who falls in love with a non-Greek protestant fellow, Ian Miller. Toula is the only one in her family who had not met her family expectations of marrying a Greek and having children. Toula is stuck working in the family business, a restaurant, and her sister has the perfect Greek family. Toula's father is adamantly opposed to marriage to a non-Greek. A wedding is eventually planned with multiple problems throughout the year.

VIEWING POINTS: Discuss the stigma that faces Toula and Ian as they plan their life together. How would you intervene if Toula approached you for help with her family? Identify the cultural beliefs that are shaping and interfering with the wishes of the newly engaged couple.

Unit IV: **Mental Health Care in Contemporary Society**

16

Mental Health Promotion for Children and Adolescents

Catherine Gray Deering

KEYCONCEPTS

- egocentric thinking
- invincibility fable

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Describe common stressors for children and adolescents.
2. Identify risk factors for the development of psychopathology in childhood and adolescence.
3. Describe protective factors in the mental health promotion of children and adolescents.
4. Analyze the role of the nurse in mental health promotion for children and families.

KEY TERMS

- Adverse childhood events
 - Attachment
 - Bibliotherapy
 - Bullying
 - Child abuse and neglect
 - Developmental delays
 - Early intervention programs
 - Family preservation
 - Fetal alcohol syndrome
 - Formal operations
 - Normalization
 - Protective factors
 - Psychoeducational programs
 - Relational aggression
 - Resilience
 - Risk factors
 - Social skills training
 - Vulnerable child syndrome
-

INTRODUCTION

Children and adolescents respond to the stresses of life in different ways according to their developmental levels. **Resilience** is the phenomenon by which some children at risk for psychopathology—because of genetic or experiential circumstances (or both)—attain good mental health, maintain hope, and achieve healthy outcomes (Garcia-Dia et al., 2013). This chapter examines specific determinants of childhood and adolescent mental health, discusses the effects of common childhood stressors, and identifies **risk factors** for psychopathology, or the characteristics that increase the likelihood of developing a disorder. This chapter also considers **protective factors**, or the characteristics that reduce the probability that a child will develop a disorder, and provides guidelines for mental health promotion and risk reduction. Over the past two decades, a large body of research on diverse populations has established a strong connection between **adverse childhood events** (e.g., abuse, neglect, domestic violence,

household substance abuse and mental illness, parental separation or divorce, and incarceration of family members) and later physical and mental health problems (Hays-Grudo & Morris, 2020). Nurses are in a key position to identify and intervene with children and adolescents at risk for psychopathology by virtue of their close contact with families in health care settings and their roles as educators. Knowing the difference between typical and atypical child development is crucial in helping parents to view their children's behavior realistically and to respond appropriately.

CHILDHOOD AND ADOLESCENT MENTAL HEALTH

Supportive social networks and positive childhood and adolescent experiences maximize the mental health of children and adolescents. Children are more likely to be mentally healthy if they have good physical health, positive social development, an easy temperament (adaptable, low intensity, and positive mood), and secure **attachment** through the emotional bonds formed between them and their parents at an early age. These areas are considered in the mental health assessment of children (see Chapter 36). **Developmental delays** not only slow the child's progress but also can interfere with the development of positive self-esteem. Children with an easy temperament can adapt to change without intense emotional reactions. A secure attachment helps the child test the world without fear of rejection.

NCLEXNOTE Attachment and temperament are key concepts in the behavior of children and adolescents in any health care setting. Apply these concepts to any pediatric patient.

COMMON PROBLEMS IN CHILDHOOD

Children and adolescents are faced with many challenges while growing up. Loss is an inevitable part of life. All children experience significant losses, the most common being death of a grandparent, parental divorce, death of a pet, and loss of friends through moving or changing schools. Learning to mourn losses can lead to a renewed appreciation of the precious value of life and close

relationships. Sibling rivalry, illness, and common adolescent risk-taking tendencies also may pose challenges for children as they grow and develop.

Death and Grief

Vast research shows that similar to adults, children who experience major losses are at risk for mental health problems, particularly if the natural grieving process is impeded. However, the grieving process differs somewhat between children and adults ([Table 16.1](#)).

Table 16-1: Grieving in Childhood, Adolescence, and Adulthood

Children	Adolescents	Adults
View death as reversible; do not understand that death is permanent until about age 7 years. Experiment with ideas about death by killing bugs, staging funerals, acting-out death in play.	Understand that death is permanent but may flirt with death (e.g., reckless driving, unprotected sex) because of omnipotent feelings. May be fascinated by death, enjoy morbid books and movies, listen to rock music about death and suicide.	Understand that death is permanent; may struggle with spiritual beliefs about death. May try not to think about death, depending on cultural background.
Mourn through activities (e.g., mock funerals, playing with things owned by the loved one); may not cry.	Mourn by talking about the loss, crying, and reflecting on it, sometimes becoming dramatic (e.g., overidentifying with the lost person, developing poetic or romantic ideas about death).	Mourn through talking about the loss, crying, reviewing memories, and thinking privately about it.
May not discuss the loss openly but may instead express grief through regression,	Often withdraw when mourning or seek comfort through peer groups; may feel parents do not understand	Usually discuss loss openly, depending on level of support available; may feel there is a “time limit”

somatic complaints, their feelings.
behavior problems, or
withdrawal.

Need repeated
explanations to fully
understand the loss; it
may be helpful to read
children's books that
explain death.

Need permission to grieve
openly because they may
believe they should act strong
or take care of the adults
involved; need acceptance of
their sometimes extreme
reactions.

on how long it is socially
acceptable to grieve.

Need friends, family, and
other supportive people to
listen and allow them to
mourn for however long it
takes; need opportunities to
review their feelings and
memories.

Children's responses to loss reflect their developmental level. As early as age 3 years, children have some concept of death. For example, the death of a goldfish provides an opportunity for the child to grasp the idea that the fish will never swim again. However, not until about age 7 years can most children understand the permanence of death. Before this age, they may verbalize that someone has "died" but in the next sentence ask when the dead person will be "coming back". Some adolescents, age 11 to 18, may believe they are immune to death and engage in risky behaviors, such as driving dangerously. This phenomenon is known as the *invincibility fable* because adolescents view themselves in an egocentric way, as unique and invulnerable to the consequences experienced by others.

KEYCONCEPT The **invincibility fable** is an aspect of **egocentric thinking** in adolescence that causes teens to view themselves as immune to dangerous situations, such as unprotected sex, fast driving, and drug abuse.

If the concept of death is difficult for adults to grasp, it is particularly important to be sensitive to children's struggle to understand and cope with it. Most children closely watch their parents' response to grief and loss and use fantasy to fill the gaps in their understanding. In many cases, family members take turns grieving, with children sensing that their parents are so overwhelmed by their own emotional pain that they cannot bear the children's grief. They also see adults taking turns being strong for each other.

Loss and Early Childhood

A child, ages 2 to 6, may react more to the parents' distress about a death than to the death itself. Young children who depend totally on their parents may be frightened when they see their parents upset. Anything the parent can do to alleviate their children's anxiety, such as reassuring them that the parent will be okay and continuing the child's routine (e.g., normal bedtimes, snacks, play times), will help the child to feel secure (Worden, 2018). Because preschool-aged children have limited ability to verbalize their feelings, they may need to express them through fantasy play and activities, such as mock funerals. Books that explain death, such as *Charlotte's Web* by E. B. White, may also be helpful. Parents should take care not to use euphemisms that could fuel misconceptions of death, such as "They went to sleep." Young children may interpret these messages literally and fear going to sleep (because they might die) or focus their natural, grief-related anger on the irrational idea that the person deliberately has not returned. The best approach is to explain honestly that the person has died and is not coming back, elicit the child's understanding and questions about what has happened, and then repeat this process continually as the child gradually begins to grasp the reality of the situation. The decision of whether to take a young child to a funeral may be particularly complex. [Figure 16.1](#) enumerates some factors to consider.

Loss and the Middle Childhood Years

Children, age 6 to 11, understand the permanence of death more clearly than do younger children age 2 to 6, but they may still struggle to articulate their feelings. Children in this age group, age 6 to 11, may express their grief through somatic complaints, regression, behavior problems, withdrawal, and even anger toward their parents. They may think that others expect them to cry and react with immediate emotional intensity to the death; when they do not react this way, they feel guilty.

The death of a sibling can be a particularly difficult loss for both the child and the family. Common reactions to this are for the surviving child to feel guilt because of natural sibling rivalry and for the parents to unconsciously endow the surviving child with qualities of the lost sibling as if to fill the empty space in the family (Worden, 2018). Of course, the death of a parent can be even more devastating. The surviving parent's psychological functioning has a major impact on the child's adjustment to the loss (Bugge et al., 2014). Parents should

provide grieving children with support, nurturance, continuity, and the opportunity to remember the lost person in concrete ways through photographs, stories, and family activities that allow the child to memorialize the loved one.

Loss and Adolescents

Adolescents who are in Piaget stage of **formal operations**, characterized by the ability to use abstract reasoning to conceptualize and solve problems, can better understand death as an abstract concept (see [Chapter 7](#)). Because adolescents tend to be idealistic and to think in extremes, they may even have poetic or romantic notions about death. Many teenagers become fascinated with morbid rock music, movies, and books. Although they may be able to express their thoughts and feelings about death more clearly than younger children, they often are reluctant to do so for fear of being viewed as childish. Some adolescents assume a parental role in the family after a death, denying their own needs. School settings may be particularly helpful in providing group and individual support for grieving adolescents who may fear being viewed as different from their peers (Lytje, 2017). Structured programs for children and adolescents can prevent complicated (pathologic) bereavement.

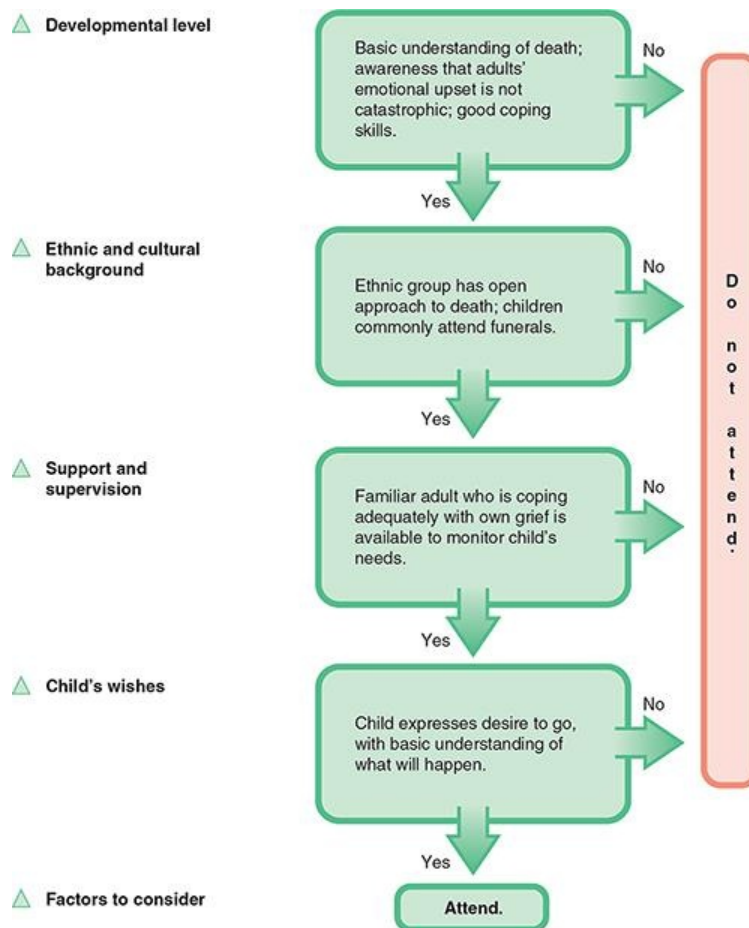

FIGURE 16-1: Decision tree: Should a child attend a funeral? (pixelheadphoto digitalskillet/Shutterstock.)

Separation and Divorce

Although many families adapt to separation and divorce without long-term negative effects for the children, youth often show at least temporary difficulties in dealing with this common stressor (Demir-Dagnas, 2020). Parental separation and divorce change the family structure, usually resulting in a substantial reduction in the contact that children have with one of their parents. The child's response to divorce is similar to the response to death. In some ways, divorce may be harder for the child to understand because the noncustodial parent is gone but still alive, and the parents have made a conscious choice to separate. Children of divorce are at increased risk for emotional, behavioral, and academic problems. However, the response to the loss that divorce imposes varies

depending on the child's temperament; the parents' interventions; and the level of stress, change, and conflict surrounding the divorce (Hetherington & Kelly, 2002). A major change in socioeconomic status, such as moving from dual-earner status to single-parent family status, may account for much of the variation in levels of distress among divorcing families (Ryan & Claessens, 2013).

The first 2 or 3 years after the couple's breakup tend to be the most difficult. Typical childhood reactions include confusion, guilt, depression, regression, somatic symptoms, acting-out behaviors (e.g., stealing, disobedience), fantasies that the parents will reunite, fear of losing the custodial parent, and alignment with one parent against the other. After an initial adjustment period, children usually accept the reality of the situation and begin coping adaptively. Most divorced parents eventually remarry new partners, which often imposes another period of coping difficulties for the children. Children with stepparents and stepsiblings are at renewed risk for emotional and behavioral problems as they struggle to cope with the new relationships (Browning & Artelt, 2014).

Protective factors against emotional problems in children of divorce and remarriage include a structured home and school environment with reasonable and consistent limit setting and a warm, supportive relationship with stepparents (Kelly, 2012). Helpful interventions for children of divorce include education regarding children's reactions; promotion of regular and predictable visitation; reduction of conflict between the parents through counseling, mediation, and clear visitation policies; continuance of usual routines; and family counseling to facilitate adjustment after remarriage (Table 16.2). It is also important to make it clear to children that the divorce was not caused by them. Egocentric thinking, which is normal for children, may cause children to believe that they are at the root of the problem. Some evidence shows that it is not the divorce itself but rather the continuing conflict between the parents that is most damaging to children (Havermans et al., 2014). Parents manage divorce better if they can remember that children naturally idealize and identify with both parents and need to view both of them positively. Therefore, it is helpful for parents to guard against making negative statements about each other and focus on evidence of their former partner's love and respect for the child.

Table 16-2: Play Therapy with a 4-Year-Old Child Whose Parents are Divorcing

Patient

Statement Nurse Response

Analysis and Rationale

(Child smashes two cars together and makes loud, crashing sound.)	That's a loud crash. They really hit hard.	Child may be expressing anger and frustration nonverbally through play. Nurse attempts to establish rapport with child by relating at child's level using age-appropriate vocabulary.
Crrrash!	I know a boy who gets so mad sometimes that he feels like smashing something.	Child is engrossed in fantasy play, typical of preschoolers. Children often use toys as symbols of human figures (animism). Nurse uses indirect method of eliciting child's feelings because preschoolers often do not express feelings directly. Reference to another child's anger helps to normalize this child's feelings.
Yeah!	Sounds like you feel that way sometimes, too.	Child is beginning to relate to nurse and sense her empathy. Nurse reflects the child's feelings to facilitate further communication.
Yeah, when my mom and dad fight.	It's hard to listen to parents fighting. Sometimes, it's scary. You wonder what's going to happen.	Child is experiencing frustration and helplessness related to family conflict. Nurse expresses empathy and attempts to articulate child's feelings because preschool children have a limited ability to identify and label feelings.
My mom and dad are getting a divorce.	That's too bad. What's going to happen when they get the divorce?	Child has basic awareness of the reality of parents' divorce but may not understand this concept. Nurse expresses empathy and attempts to assess the child's level of understanding of the divorce.
Dad is not going to live in our house.	Oh, I guess you'll miss having him there all the time. It would be nice if you all could live together, but I guess that's not going to	Preschool child focuses on the effects the divorce will have on him (egocentrism). Child seems to have a clear understanding of the consequences of the divorce. Nurse articulates the child's perspective and reinforces the reality of the divorce to avoid fueling child's possible denial and reconciliation fantasies.

	happen.	
(Silently moves cars across the floor.)	What do you think is the reason your parents decided to get a divorce?	Child expresses sadness nonverbally. Nurse further attempts to assess the child's understanding of the circumstances surrounding the divorce.
Because I did it.	What do you mean—you did it?	Child provides clue that he may be feeling responsible. Nurse uses clarification to fully assess child's understanding.
I made them mad because I left my bike in the driveway and Dad ran over it.	How? Do you think that is why they're getting the divorce?	Child uses egocentric thinking to draw conclusion that his actions caused the divorce. Nurse continues to clarify the child's thinking. The goal is to elicit the child's perceptions, so that misperceptions can be corrected.
Yeah, they had a big fight.	They may have been upset about the bike, but I don't think that is why they're getting a divorce.	The nurse goes on to explain why parents get divorced and to provide opportunities for the child to ask questions.
Why?	Because parents get divorced when they're upset with <i>each other</i> —when they can't get along—not when they're upset with their children.	

KEYCONCEPT In **egocentric thinking**, children naturally view themselves as the center of their own universe. Common examples of this are children looking out the car window at night and claiming that “the moon is following me” and children sitting in front of the television set, blocking the view for the parent, but believing that if they can see the television, the parent can, too. This kind of magical, self-focused thinking is charming, but it has a downside when children believe that they have caused a divorce or death in the family because of their own actions.

Sibling Relationships

Until recently, the role of siblings in children's development was underemphasized. A growing body of research shows that sibling relationships significantly influence personality development. Positive sibling relationships can be protective factors against the development of psychopathology (Fig. 16.2), particularly in troubled families in which the parents are emotionally unavailable (Bank & Kahn, 2014). Thus, nurses should emphasize to parents that minimizing sibling rivalry and maximizing cooperative behavior will benefit their children's social and emotional development throughout life.

Sibling rivalry begins with the birth of the second child. Often, this event is traumatic for the first child who, up until then, was the sole focus of the parents' attention (Nadelman & Begun, 2014). The older sibling usually reacts with anger and may reveal not-so-subtle fantasies of getting rid of the new sibling (e.g., "I dreamed that the new baby died."). Parents should recognize that these reactions are natural and allow the child to express feelings, both positive and negative, about the baby while reassuring the child that they have a very special place in the family. Allowing the older child opportunities to care for the baby and reinforcing any nurturing or affectionate behavior will promote positive bonding (Kramer & Ramsburg, 2002).

Some sibling rivalry is natural and inevitable, even into adulthood. However, intense rivalry and conflict between siblings correlate with behavior problems in children. However, positive temperament and effective, supportive coparenting can buffer against the negative outcomes associated with sibling conflict (Kolak & Volling, 2013). One factor that can exacerbate this sibling rivalry is differential treatment of children. Although it is natural and appropriate for parents to use different methods to manage children with different personalities, parents must be sensitive to their children's perceptions of their behavior and emphasize each child's strengths. Helping each child to develop a separate identity based on unique talents and interests can minimize rivalry and perceptions of favoritism.

FIGURE 16-2: Sibling relationships significantly influence personality development.

Children with siblings who have psychological disorders are also at increased risk for mental health problems (Ma et al., 2015) (However, recent studies suggest that siblings may be an important source of support for children with mental health problems [Bojanowski et al., 2020]), and they may provide a buffer against parental conflict in families (Davies et al., 2019). Nurses should be alert to behavior problems of other family members and include siblings in family interventions.

Bullying

Children have been victimized by bullies throughout history, but this problem has only recently become a topic of widespread concern for mental health professionals.

Bullying is defined as repeated, deliberate attempts to harm someone, usually unprovoked. An imbalance in strength is a part of the pattern, with most victims having difficulty defending themselves. Boys are more likely to use physical aggression, and bigger boys usually pick on smaller, weaker ones (Hymel & Swearer, 2015). Some studies suggest that girls are more likely to use **relational aggression**, which involves disrupting peer relationships by excluding or manipulating others and spreading rumors. Cyberbullying (spreading pictures, rumors, or smear campaigns via the Internet) has become an increasingly

common phenomenon that can have devastating effects because of the speed and scope of its impact (Carpenter & Hubbard, 2014).

Children who have insecure attachments, who have distant or authoritarian parents, and who have been physically, sexually, or verbally abused are at risk for becoming bullies (Rodkin & Hodges, 2003). On the other side, victims of bullies often suffer from low self-esteem and relationship difficulties, even into adulthood.

Nurses who work with children and adolescents should assess for the occurrence of bullying by asking direct questions because this problem is often hidden (Hensley, 2013). Immediate intervention should involve a coordinated effort by the school, parents, bullies, and victims because studies show that bullying does not occur in a vacuum. Rather, numerous “henchmen”, supporters, and bystanders participate in the process (Olweus, 2003). The most effective programs involve educating and changing the climate in the whole school (not just working with the bullies) (Nickerson, 2019).

Physical Illness

Many children experience a major physical illness or injury at some point during development. Hospitalization and intrusive medical procedures are acutely traumatic for most children. The likelihood of lasting psychological problems resulting from physical illness depends on the child’s developmental level and previous coping mechanisms, the family’s level of functioning before and after the illness, and the nature and severity of the illness. As with any major stressor, the perception of the event (i.e., meaning of the illness) will influence the family’s ability to cope. One possible outcome of early childhood illness or injury is the phenomenon of **vulnerable child syndrome**, in which the family perceives the child as fragile despite current good health, causing them to be overprotective (Duncan & Caughy, 2009).

Common childhood reactions to physical illness include regression (e.g., loss of previous developmental gains in toilet training, social maturity, autonomous behavior), sleep and feeding difficulties, behavior problems (negativism, withdrawal), somatic complaints that mask attempts at emotional expression (e.g., headaches, stomach aches), and depression. Infants and children younger than school age are particularly vulnerable to separation anxiety during illness and may regress to earlier levels of anxiety about strangers, becoming fearful of

health care providers. Young children often have magical thinking about the illness, and their tendency to process information in concrete terms may lead to misperceptions about the illness and treatment procedures (e.g., dye vs. die; stretcher vs. stretch her) (Deering & Cody, 2002). Adolescents may be concerned about body image and maintaining their sense of independence and control.

Nurses must remember that parents are the primary resource to the child and the experts who know the child's needs and reactions. Thus, nurses must maintain a collaborative approach in working with parents of physically ill children. If the child is a sick infant, nurses should take care to allow the normal attachment process between parents and the infant to unfold, despite health care professionals' efforts to assume some parenting functions.

Many parents react with guilt to their child's illness or injury, especially if the illness is genetically based or partially the result of their own behavior (e.g., drug or alcohol abuse during pregnancy). Parents may project their guilt onto each other or health care professionals, lashing out in anger and blame. Nurses should view this behavior as part of the grieving process and help parents to move forward in caring for their children and regaining competence. Teaching parents how to care for their children's medical problems and reinforcing their successes in doing so will help.

Chronic physical illness in childhood presents a unique set of challenges. Although most children with chronic illnesses and their families are remarkably resilient and adjust to the stressors and regimens involved in their care, children with chronic health conditions are significantly more likely to experience psychiatric symptoms than are their healthy peers (Secinti et al., 2017). Conditions that affect the central nervous system (CNS) (e.g., infections, metabolic diseases, CNS malformations, brain and spinal cord trauma) are particularly likely to result in psychiatric difficulties. Nurses who understand pathophysiologic processes are in a unique position to assess the interaction between biologic and psychological factors that contribute to mental health problems in chronically ill children (e.g., lethargy from high blood sugar levels or respiratory problems, mood swings from steroid use). Inactivity and lack of sensory stimulation from hospitalization or bed rest may contribute to neurologic deficits and developmental delays.

The major challenge for a chronically ill child is to remain active despite the limitations of the illness and to become fully integrated into school and social activities. Children who view themselves as different or defective will

experience low self-esteem and be more at risk for depression, anxiety, and behavior problems. Studies show that parental perceptions of the child's vulnerability predict greater adjustment problems even after controlling for age and disease severity (Anthony et al., 2003). Educating parents and helping them to foster maximum independence within the limitations of the child's health problem is the key. Nurses in primary care settings are in a good position to promote integrated mental health care to children with physical health problems.

Adolescent Risk-Taking Behaviors

Adolescence is a time of growing independence and, consequently, experimentation. Emotional extremes prevail. To adolescents, the world seems great one day and terrible the next; people are either for them or against them. Adolescents are struggling to consolidate their abilities to control their impulses and react to the many "crises" that may seem trivial to adults but are very important to teens. Biologic changes (e.g., onset of puberty, height and weight changes, hormonal changes), psychological changes (increased ability for abstract thinking), and social changes (dating, driving, increased autonomy) are all significant. Unevenness in adolescent brain development, specifically in the amygdala, may contribute to difficulties with impulse control or the ability to "think twice" before acting (Steinberg, 2019).

Teenagers test different roles and struggle to find a peer group that fits their unfolding self-image. During this process, many adolescents experiment with risk-taking behaviors, such as smoking, using alcohol and drugs, having unprotected sex, engaging in truancy or delinquent behaviors, and running away from home. Although most youths eventually become more responsible, some develop harmful behavior patterns and addictions that endanger their mental and physical health. One recent trend is self-mutilation or cutting by adolescents who use this as a cry for help or a tension release (Askew & Byrne, 2009; Lloyd-Richardson et al., 2020). Adolescents whose psychiatric problems have already developed are particularly vulnerable to engaging in risky behaviors because they have limited coping skills, may attempt to self-medicate their symptoms, and may feel increased pressure to fit in with other teens.

Several approaches to mental health promotion with adolescents are recommended. First, intervening at the peer group level through education programs, alternative recreation activities, and peer counseling is most

successful. Second, training in values clarification, problem-solving, social skills, and assertiveness helps give adolescents the skills to cope with situations in which they are pressured by their peers. If just one person can find the strength to express an unpopular viewpoint in a group and decline to participate in a destructive activity, others will quickly follow. It takes enormous courage, as well as concrete knowledge and practice with assertiveness, to speak up in these situations. A third type of intervention is a program that uses team efforts by teachers, parents, community leaders, and teen role models. These programs help at-risk youth by building self-esteem, setting positive examples, and working to involve the youth in community activities.

Approaches that have not proved effective include mere education about dangerous activities without behavior training and programs that provide inadequate training for the professionals implementing them. In any intervention, it is also important to keep in mind that adolescents are skeptical of authority figures and tend to take cues from one another. Nurses working with teenagers find it helpful to use a discussion approach that encourages questioning and argument as opposed to talking down to or “talking at” teenagers (Deering & Cody, 2002).

RISK FACTORS FOR CHILDHOOD PSYCHOPATHOLOGY

Understanding the risk factors for psychopathology is vital in mental health promotion and the prevention of disorders. Any intervention must recognize and work to address these factors if it is to be successful.

Poverty and Homelessness

Children are born into their parents’ socioeconomic class, and the effects of intergenerational poverty impact all aspects of their development (Miller-Smith, 2020). Lack of proper nutrition and access to prenatal and infant care places children from poor families at risk for physical and mental health problems. Adolescence may be truncated when children from impoverished families are forced into adult roles as parents work long hours to meet basic needs (Dashiff et

al., 2009; see [Chapter 15](#)).

Although crime, drug abuse, gang activity, and teenage pregnancy are seen in adolescents from all socioeconomic backgrounds, children living in poverty may be more vulnerable to these problems because they may view their options as limited. Thus, they may have an increased need to maintain a tough image and struggle more for a sense of control over their environment. The obstacles inherent in overcoming the effects of poverty can seem insurmountable to young people.

A major focus of preventive nursing interventions for disadvantaged families involves simply forming an alliance that conveys respect and willingness to work as an advocate to help patients gain access to resources. In terms of Maslow need hierarchy, families living in poverty may be more focused on survival needs (e.g., food, shelter) than self-actualization needs (e.g., insight-oriented psychotherapy for themselves or their children). Unless the nurse can work as a partner with the family and address the issues that are most pressing for the family with an active, problem-solving approach, other types of intervention may be fruitless. At the same time, it is inappropriate to assume that poor families will be resistant to or unable to benefit from psychotherapy or other mental health interventions.

Additional risks arise from homelessness in children and teens, which may result from loss of shelter for the entire family, running away, or being thrown out of their homes ([Box 16.1](#)> see also Chapter 41). For youths who are homeless, there is an increased risk for physical health problems (e.g., nutrition deficiencies, infections, chronic illnesses), mental health problems (particularly developmental delays in language, fine or gross motor coordination, and social development; depression; anxiety; disruptive behavior disorders), and educational underachievement. Many homeless youth have been physically and/or sexually abused, leading to elevated rates of mental disorders (Wong et al., 2016). Adolescents who run away from an abusive home can find themselves living on the streets where staying alive and developing self-reliance are a daily struggle.

The living conditions of many shelters place children at risk for lead poisoning and communicable diseases and make the regular sleep, feeding, play, and bathing patterns important for normal development nearly impossible. Nurses working with homeless families need to be aware of the effects of this lifestyle on children because they have a limited ability to speak for themselves and because their needs are often overlooked.

Child Abuse and Neglect

Early recognition and reduction of risk factors are the keys to preventing **child abuse and neglect**, which includes any actions that endanger or impair a child's physical, psychological, or emotional health and development. Risk factors for child abuse and neglect include high levels of family stress, drug or alcohol abuse, a stepparent or parental boyfriend or girlfriend who is unstable or unloving toward the child, and lack of social support for the parents. In addition, young children (particularly those younger than 3 years) and children with a history of prematurity, medical problems, and severe emotional problems are at high risk because they place great demands on their parents. Abuse can have lifelong effects on development. Children who have been maltreated are more likely to enter aggressive relationships, abuse drugs or alcohol to numb emotions, develop eating disorders, become depressed, and engage in self-destructive behavior (Kolko & Berkout, 2017).

Attention, Externalizing, and Internalizing Problems of Youth Exposed to Parental Incarceration

Boch, S. J., Warren, B. J. W., & Ford, J. L. (2019). Attention, externalizing, and internalizing problems of youth exposed to parental incarceration. *Issues in Mental Health Nursing*, 40(6), 466–475.

THE QUESTION: How does parental incarceration affect children's mental health, and how does exposure to additional adverse childhood experiences (ACEs) influence these outcomes?

METHODS: Nurse researchers examined data from a sample of adolescents in a racially, ethnically, and socioeconomically representative area of a Columbus, Ohio (n = 613). Face-to-face interviews were conducted in the home, along with surveys of adolescents and their caregivers. The researchers performed regression analyses to answer to their questions.

FINDINGS: Youth who were exposed to parental incarceration were more likely to have their caregiver-report attention, internalizing (e.g., depression, anxiety), externalizing (e.g., disobedience, anger), and total problem behaviors, after controlling for socioeconomic characteristics. Youth exposed to parental incarceration experienced an average of 15 additional ACEs compared with their unexposed peers, who averaged 4 ACEs.

IMPLICATIONS FOR NURSING: The nurse researchers conclude that the experience of parental incarceration may be viewed as a marker of accumulative risk for mental health problems in youth. The combination of the incarceration and the increased exposure to additional ACEs has an apparent cumulative effect. The ACEs may be part of the pathway toward incarceration (e.g., poverty, parental substance abuse) or a direct consequence of the incarceration (e.g., loss of parent, out-of-home placement). Either way, this vulnerable population needs additional screening, trauma-

informed care, and interventions. The article cites other research showing that one in every 14 youth in the United States has experienced parental incarceration. Nurses should screen for ACEs among youth whose parents have been incarcerated and work with community or school organizations to implement evidence-based interventions.

Nurses are legally mandated to report any reasonable suspicion of abuse and neglect to the appropriate state authorities. [Box 16.2](#) lists signs of physical and sexual abuse in children. Mandated reporting laws allow the state to investigate the possibility of abuse, provide protection to children, and link families with support and services. Nurses are immune from liability for reporting suspected abuse, but they may be held legally accountable for not reporting it. The decision to report abuse sometimes poses an ethical dilemma for nurses as they try to balance the need to maintain the family's trust against the need to protect the child. This decision is further complicated by the knowledge that if temporary out-of-home placement is necessary, the quality of the placement may not be optimum, and the child and family may suffer in the process of the separation.

Box 16.2

Signs of Possible Child Abuse

SEXUAL ABUSE

- Bruises or bleeding on the genitals or in the rectum
- Sexually transmitted infection (e.g., HIV, gonorrhea, syphilis, herpes genitalis)
- Vaginal or penile discharge
- Sore throats
- Enuresis or encopresis
- Foreign bodies in the vagina or rectum
- Pregnancy, especially in a young adolescent
- Difficulty in walking or sitting
- Sexual acting out with siblings or peers
- Sophisticated knowledge of sexual activities
- Preoccupation with sexual ideas
- Somatic complaints, especially abdominal pain and constipation
- Sleep difficulties
- Hyperalertness to the environment
- Withdrawal
- Excessive daydreaming or seeming preoccupied
- Regressed behavior

PHYSICAL ABUSE

- Bruises or lacerations, especially in clusters on back, buttocks, thighs, or large areas of the torso
- Fractures inconsistent with the child's history
- Old and new injuries at the same time

- Unwilling to change clothes in front of others; wears heavy clothes in warm weather
- Identifiable marks from belt buckles, electrical cords, or handprints
- Cigarette burns
- Rope burns on arms, legs, face, neck, or torso from being bound and gagged
- Adult-size bite marks
- Bald spots interspersed with normal hair
- Shrinking at the touch of an adult
- Fear of adults, especially parents
- Apprehensive when other children cry
- Scanning the environment, staying very still, failing to cry when hurt
- Aggression or withdrawal
- Nondiscriminatory seeking of affection
- Defensive reactions when questioned about injuries
- History of being taken to many different clinics and emergency departments for different injuries

*Note. Because many injuries do not represent child abuse, a careful history must be taken.

To minimize damaging the nurse–family relationship, experts recommend that nurses report abuse in the presence of the parents, preferably with the parent initiating the telephone call. The professional should explain that reporting is necessary to provide safety for the child and to obtain services for the family. If the parents cannot be present when the report is made, the nurse should, at minimum, notify the family that the report was made.

Preventing child abuse and neglect occurs with any intervention that supports the parents with physical, financial, mental health, and medical resources that will reduce stress within the family system. Early intervention and family support programs are considered the cornerstone of preventive efforts. A major protective factor against psychopathology stemming from abuse and neglect is the establishment of a supportive relationship with at least one adult who can provide empathy, consistency, and possibly, a corrective experience (e.g., a foster parent or other family member) for the child (Yoon et al., 2019).

Nurses working with abused children should resist the temptation to view the child as the only victim. Remembering that most abusive parents were abused as children and therefore may have limited coping mechanisms or little access to positive parental role models will help the nurse keep empathy toward the parents. After state agencies intervene to establish the child’s safety, a family systems approach that is supportive of the whole family unit is most effective.

Substance-Abusing Families

Children whose parents are substance abusing (see Chapter 31) live in an unpredictable family environment, coping with stress that may disrupt their ability to perform in school and lead to other emotional problems. The codependency movement, which emphasizes the effects of addiction on family members and groups such as Adult Children of Alcoholics and Al-Anon, has brought increasing attention to the effects of parental substance abuse on child development.

Biologic factors affecting children of those who abuse substances include **fetal alcohol syndrome**, nutritional deficits stemming from neglect, and neuropsychiatric dysfunction (Hughes et al., 2019). Genetic factors are at least partly responsible for the well-documented increased risk for substance abuse among children whose parents abuse substances. Recent studies are beginning to link a family history of anxiety disorders and alcoholism with genetically transmitted anxiety disorders, which may be a precursor to alcohol abuse. The precise mechanism of family transmission of alcoholism is still unknown. Recent studies suggest that children of those who abuse substances may inherit a predisposition to a nonspecific form of biologic dysregulation that may be expressed either as alcoholism or some other psychiatric disorder (e.g., hyperactivity, conduct disorder, depression), depending on the individual's developmental history.

Children of those who abuse substances are at high risk for both substance abuse and behavior disorders (Straussner & Fewell, 2011). Moreover, some evidence shows that other factors related to addiction, such as family stress, violence, divorce, dysfunction, and other concurrent parental psychiatric disorders (e.g., depression, anxiety), are as important as the substance abuse itself in increasing this risk (Ritter et al., 2002). The experience of growing up in a substance-abusing family is marked by unpredictability, fear, and helplessness because of the cyclic nature of addictive patterns.

Even for children who do not experience significant psychopathology, the experience of growing up in a substance-abusing family can lead to a poor self-concept when children feel responsible for their parents' behavior, become isolated, and learn to mistrust their own perceptions because the family denies the reality of the addiction. The recent upsurge in opioid abuse has posed particular challenges for families (Sapp & Hooten, 2019). The experience of growing up with an opioid-addicted parents has been characterized as living with ambiguous loss, as the parent may be physically present but psychologically absent due to preoccupation with obtaining and using the drug (Mechling et al.,

2018). Despite the well-documented risk for children in substance-abusing families, there is no uniform pattern of outcomes, and many children prove resilience. School-based interventions with children from substance-abusing families can significantly increase resilience (Gance-Cleveland & Mays, 2008).

Out-of-Home Placement

The tendency to blame parents and view out-of-home placement as a refuge for children has sharply declined in recent years. This change in attitudes results from public awareness of the deficiencies in the foster care system, greater support for parents' rights, and increased knowledge of the biologic basis for many of the disorders of parents and children that lead to out-of-home placement. **Family preservation** involves supporting and educating the family to secure the attachment between children and parents and to preserve the family unit and prevent the removal of children from their homes. Today, children are removed from their homes only as a last resort. Family support services are designed to assist families with access to resources and education regarding child-rearing, monitor and facilitate the development of the bond between child and caregiver, and increase the caregiver's confidence in their abilities (Turnbull et al., 2007).

However, despite latest trends toward family preservation, an increasing number of children are placed in foster homes, group homes, or residential treatment centers—in many cases for months to years (Bruskas, 2008). Factors leading to the increased number of children in out-of-home placement include increased willingness of the public and professionals to report child abuse and neglect; the epidemic proportions of substance abuse and cases of acquired immunodeficiency syndrome; and the increasing number of families living in poverty. Those may lead to abuse, neglect, and homelessness. About 50% of children in out-of-home placement are adolescents, but the numbers of infants and young children are growing, particularly those with serious physical and emotional problems, who pose particular challenges for placement (Scribano, 2010). Infants who are abandoned by drug-abusing parents and children with human immunodeficiency virus (HIV) whose parents are sick or deceased need permanent out-of-home placements, which are often difficult to find. When children with mental health needs are placed in foster care, a family support team is required to meet regularly, with the goal of providing holistic care,

avoiding overuse of psychotropic medication, and moving toward a permanent placement that will provide stability (Bertram, 2018).

The adjustment to an out-of-home placement can be viewed through the conceptual framework of Bowlby's stages of coping with parental separation. According to Bowlby (1960), the child initially responds to separation from parents with protest (crying, kicking, screaming, pleading, and attempting to elicit the parent's return). The child then moves to a state of despair (listlessness, apathy, and withdrawal, which lead to some acceptance of caregiving by others but a reluctance to reattach fully). Finally, the child experiences detachment if the child and new parent cannot manage to form an emotional bond. Because children often experience multiple placements, the potential for a disrupted attachment may be great by the time the child faces the prospect of a permanent family. After repeatedly undergoing separation and mourning, the child learns that rejection is inevitable and may automatically maintain distance from a new caregiver.

Typical coping styles seen in children exposed to multiple placements include detachment, diffuse rage, chronic depression, antisocial behavior, low self-esteem, and chronic dependency or exaggerated demands for nurturing and support. Sometimes, these symptoms develop into attachment disorders that can be difficult to treat. It takes a very committed and resilient parent to continue caring for a child who does not reinforce attempts at caregiving and who exhibits these kinds of significant emotional and behavior problems.

INTERVENTION APPROACHES

The goal of health promotion and prevention interventions is to maximize the mental health of children and adolescents. The selected interventions should allow maximal autonomy for the child and family; keep the family unit intact, if possible; and provide the appropriate level of care to meet the needs of the child and family. A view of parents as partners is important to effective interventions. Interdisciplinary approaches are ideal in which the nurse acts as coordinator, case manager, and advocate to establish linkages with physicians and nurse practitioners, teachers, speech and language specialists, social workers, and other professionals to develop and implement a comprehensive biopsychosocial plan of intervention (Box 16.3>). Support groups are available for every kind of stressor that a family can experience, including substance abuse, death, divorce,

and coping with a chronic illness. A continuum of modalities of care is available to children and families ([Fig. 16.3](#)).

Early intervention programs offer regular home visits, support, education, and concrete services to those in need. The assumption underlying these programs is that parents are the most consistent and important individuals in children's lives, and they should be afforded the opportunity to define their own needs and priorities. With support and education, parents are empowered to respond more effectively to their children. The effectiveness of these programs may be the key to preventing the placement of children outside the home (Heckman, 2013).

Psychoeducational programs designed to teach parents and children basic coping skills for dealing with various stressors are a particularly effective form of mental health intervention. By focusing on **normalization** (teaching families normal behaviors and expected responses) and providing families with information about typical child development and expected reactions to various stressors, families feel less isolated, know what to expect, and put their reactions into perspective. For example, if families learn that anger is a natural part of grieving, they will be less likely to view it as abnormal and more likely to accept and cope with it constructively.

Social skills training is useful with youth who have low self-esteem or aggressive behavior or who are at high risk for substance abuse (Bloomquist, 2013; Kvarme et al., 2010). Social skills training involves instruction, feedback, support, and practice with learning behaviors that help children to interact more effectively with peers and adults. When combined with assertiveness training, social skills training can be particularly helpful in providing children with coping skills to resist engaging in addictive or antisocial behaviors and to prevent social withdrawal under stress. Social skills training may be particularly helpful for children who are bullies or who are rejected by their peers (Fopma-Loy, 2000).

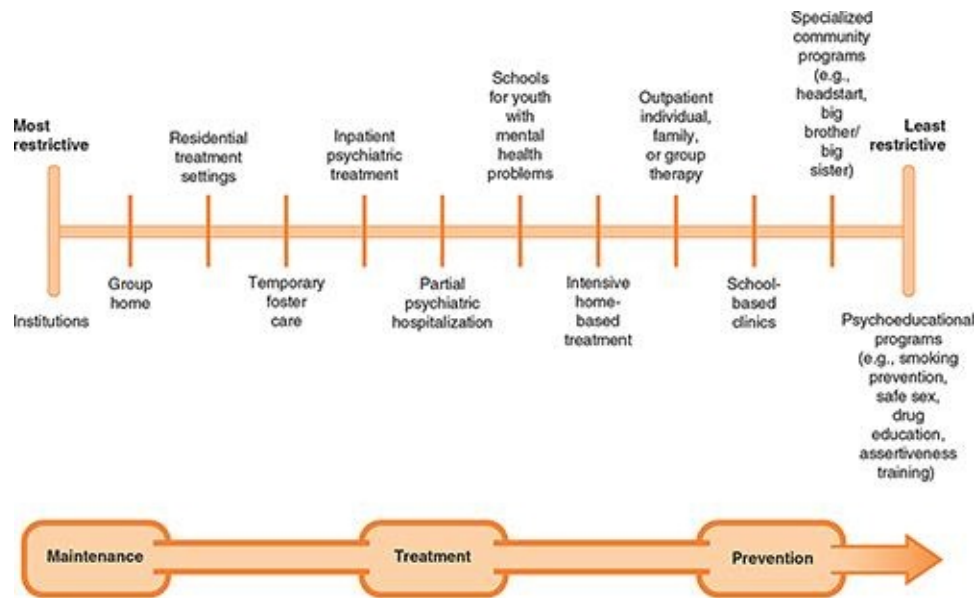

Figure 16-3: The continuum of mental health care for children and adolescents.

Box 16.3

Preventive Interventions with an Adolescent in Crisis

Ben and Rita were just transferred to a second foster home after being removed from their mother's care when she relapsed on cocaine and left them unattended. The plan is for the two children to return to their mother's home after she completes a 30-day drug treatment program. Ben, a high school freshman, is in the school nurse's office asking for aspirin for another headache.

The nurse notices that Ben's nose looks inflamed, he is sniffing, and he seems more "hyper" than usual. In a concerned tone of voice, she asks him if he has been using cocaine, and he snaps back, "Just because my mother's a coke head doesn't give you the right to suspect me!" When the nurse gently says, "Tell me about what's been happening with your mother; I had no idea," Ben responds less defensively and explains the situation about the foster home and his mother's drug problem. He says that if it weren't for Rita, his younger sister, he would have run away by now. His foster parents are "making him" go to school, but he's going to drop out as soon as he returns to live with his mother. The only thing that he likes about school is playing basketball, and the basketball coach, who is his physical education teacher, wants him on the team.

After a lengthy talk with Ben, the nurse finishes the assessment interview and concludes that he is at risk for drug abuse, running away, and dropping out of school. He is also showing symptoms of depression, which he may be attempting to medicate with cocaine. Protective factors for Ben include his strong attachment to his sister, his ability and willingness to express his thoughts and feelings, his interest in basketball, and a positive relationship with the basketball coach.

The nurse develops a plan with Ben to attend the weekly drug and alcohol discussion group at the school, so he can talk with other teens from substance-abusing families and learn coping skills to prevent addiction. The nurse contacts the basketball coach, who agrees to find a student mentor who can shoot hoops with Ben and help him come up with a plan to stay in school, maybe find a part time job, and join the basketball team. Ben agrees to check in regularly with the nurse to report how the plan is working and revise it if needed. The nurse feels optimistic that with support from his peers, coach, mentor, and herself,

Ben can overcome what is probably a genetically based risk for depression and addiction. Ben shows signs of resilience. He is motivated to “keep his act together for Rita”, capable of forming positive attachments, and willing to seek help when he knows where to find it.

WHAT DO YOU THINK?

- If Ben “forgets” to check in regularly with the nurse, what would be the next course of action?
- When are the times Ben is most susceptible to change his mind about staying in school and avoiding drugs? What action should be taken to avoid these times?

A wide variety of books are available to help children understand issues such as death, divorce, chronic illness, stepfamilies, adoption, and birth of a sibling. In addition, many mental health organizations and public health agencies have pamphlets designed to educate parents about various physical and psychological problems. By supplying concrete information and advice, these reading materials help to reduce anxiety by pointing out common reactions to the various stressors, so that families do not feel alone.

SUMMARY OF KEY POINTS

- Children who experience major losses, such as death or divorce, are at risk for developing mental health problems.
- Sibling relationships have significant effects on personality development. Positive sibling relationships can be protective factors against the development of mental health problems.
- Bullying is a severe problem that is often hidden yet can cause long-standing psychological harm; it must be addressed on a school-wide level.
- Medical problems in childhood and adolescence may cause psychological problems when illness leads to regression or lack of full participation in family, school, and social activities.
- Striving for identity and independence may lead adolescents to take part in high-risk activities (e.g., drug use, unprotected sex, smoking, delinquent behaviors) that may lead to mental health problems.
- Poverty, homelessness, abuse, neglect, and parental substance abuse all create conditions that undermine a child’s ability to make normal developmental

gains and contribute to vulnerability for various emotional and behavioral problems.

- Children who experience disrupted attachments because of out-of-home placements may have difficulty forming close relationships with their new parents and trusting others.
- Family support services and early intervention programs are designed to prevent removal of the child from the family because of abuse or neglect and to keep a strong, nurturing family system.
- Psychoeducational approaches, such as training opportunities, group experiences, and **bibliotherapy**, provide children and families with the information and skills to promote their own mental health.

CRITICAL THINKING CHALLENGES

1. Analyze a case of a family that is grieving a loss and compare the parents' and children's reactions. Include an evaluation of how each child's reactions differ, depending on their developmental level.
2. Watch a movie or read a book that provides a child's view of death, divorce, or some other loss and consider how adults may be insensitive to the child's reactions.
3. Examine your own developmental history and pinpoint periods when stressful life events might have increased the risk for emotional problems for you or other family members. What protective factors in your own personality and coping skills and in the environment around you helped you to maintain your good mental health?
4. What aspects of life are more stressful for children than for adults? (i.e., How is it different to experience life as a child?)
5. Examine how your own social and cultural background may either facilitate or create barriers to your ability to interact with families from other ethnic groups or those who are poor or homeless.
6. Allow yourself to reflect on how your own judgmental attitudes might interfere with your ability to communicate effectively with families who have abused or neglected their children.
7. Why is the process of normalization of feelings such a powerful intervention

with children and families? What kinds of mental health issues, developmental processes, or both would benefit from teaching related to normal reactions? How can nurses incorporate this kind of intervention into their practice roles?

3. How can nurses expand their roles to have maximal effects on primary, secondary, and tertiary mental health intervention with children and families?

Movie Viewing Guides

Precious: 2009. This powerful and disturbing movie portrays the life of an African American adolescent girl who is physically, sexually, and emotionally abused by her family. It shows the devastating effects of abuse, poverty, substandard schooling, and family dysfunction, at the same time conveying hope through this girl's amazing resilience.

VIEWING POINTS: Give some examples of how *Precious* uses dissociation to cope with her abuse. What are some of the effective and ineffective interventions illustrated by the professionals interacting with *Precious*? Explain how *Precious* illustrates resilience.

Because of Winn Dixie: 2005. This is a heart-rending account of Opal, a 10-year-old girl who overcomes her loneliness after moving to a small town by adopting a dog and reaching out to people in her new community. The movie explores such issues as parental separation, single parenting, substance abuse, and childhood grieving.

VIEWING POINTS: Describe how Opal's grieving process is typical of school-aged children and how it differs from that of her father. What aspects of her coping show resilience? Explain the importance of Opal's dog, Winn Dixie, in the healing process for this family. Discuss how pets may play a key role in the mental health of children. How is the relationship with a pet similar and different from the role of a sibling?

Mental Health Promotion for Young and Middle-Aged Adults

Mary Ann Boyd

KEYCONCEPTS

- middle adulthood
- young adulthood

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Describe psychosocial challenges common to young and middle-aged adults.
2. Identify risk factors related to psychopathology in young and middle-aged adults.
3. Describe protective factors in the mental health promotion of young and middle-aged adults.
4. Analyze the role of the nurse in mental health promotion for young and middle-aged adults.

KEY TERMS

- Empty nest
- Informal caregivers
- Protective factors
- Risk factors
- Sandwich generation

INTRODUCTION

Young adulthood and middle adulthood are relatively new concepts. In 1900, life expectancy was age 47 (Centers for Diseases Control and Prevention [CDC], 2010). As life expectancy increased, the middle-aged adult emerged. In 2020, life expectancy is averaging 77.8 years ranging from 72 years for Black Americans to 79.9 years for Hispanic Americans (Arias et al., 2021).

Healthy lifestyles, medical advances, and economic success contributed to longevity. U.S. families have achieved unprecedented economic stability that provides for long periods of development. Technologic advances such as economic development, improved nutrition, public health control of infectious diseases, access to health care, and other modern developments have resulted in the lengthening of the life span chronologically in the developed world. This extended adulthood provides for an increased range of life choices, such as education; job selection; and lifestyle, including relationships, marriage, and family. Such advances do not exist worldwide because of the differences in the chronologic life span in different societies. In many nondeveloped areas, the life span is characterized by a brief childhood followed by a mature adulthood that evolves quickly into old age.

MENTAL HEALTH IN YOUNG AND MIDDLE ADULTHOOD

Psychological changes in adulthood occur slowly and subtly with age and experience, not in a fixed stepwise manner. Until the late 1900s, adult development was viewed as a relatively stationary plateau with the rapid and complex changes of childhood and adolescence forming one steep side and the declining changes of old age the other. Any rigid stage theory of adult life is oversimplifying young and middle adulthood development. Young and middle adulthood development is viewed as dynamic and multifaceted (Wahl & Kruse, 2005).

The developmental issues reported by young adults, middle-aged adults, and older adults are recurrent, taking new forms as their lives unfold. The developmental concepts of identity, intimacy, and generativity may have their initial blooming during adolescence, young adulthood, and middle age, but they continue to be renegotiated in the face of life stresses such as unemployment and changes in family structure (see [Chapter 7](#)).

KEYCONCEPT The generally accepted age range for **young adulthood** is from 18 to 44 years. **Middle adulthood** spans the period from approximately 45 to 65 years.

Chronologic age is also losing its customary social meaning, resulting in a more fluid life cycle. Traditional notions of young adulthood as a time of leaving the parental home and establishing an independent career and family life, of college education taking place during late adolescence, or of the middle adulthood parents facing the “**empty nest**”—a home devoid of children and caregiving responsibilities—are being replaced with fewer age-defined life roles.

The timing of life events such as education, marriage, childrearing, career development, and retirement is becoming less regular, and more alternatives are tolerated by society. Some people never marry, and others retire very early. Many young adults now remain in their parents’ homes while they pursue their professional education rather than strike out on their own, as was customary in previous generations. Their middle adulthood parents are often already caring for their own parents, creating the **sandwich generation**, with its responsibilities toward the older generation above and two generations of children below them. Many women choose to marry and establish a family and then return to finish

their college education when their children start school. See [Table 17.1](#) for a breakdown of marital status in the U.S. adult population.

TABLE 17-1: MARITAL STATUS OF THE U.S. ADULT POPULATION OVER THE AGE OF 15 YEARS

Marital Status	Percent of Adult Population
Married	50.4
Widowed	5.6
Divorced	9.7
Separated	1.9
Never married	32.4

U.S. Census Bureau. (2016). America's families and living arrangements: 2019.

[q=America%27s+Families+and+Living+Arrangements&page=1&stateGeo=none&searchtype=web&cssp=58](https://www.census.gov/search-results.html?q=America%27s+Families+and+Living+Arrangements&page=1&stateGeo=none&searchtype=web&cssp=58)

COMMON CHALLENGES IN ADULTHOOD

Young and middle adulthood are marked by many significant life events. Among them are leaving the primary family home for the first time, getting married (or not), and taking on new caregiving responsibilities. For adults in a breadwinning role, the prospect of unemployment can also present a major life challenge that affects their ability to be effective in other life roles.

Changes in Family Structure

The young adult and middle adulthood years are characterized by changes in family structures. Older adolescents finish school and often leave home, which alters the primary family structure. Marriage establishes new roles for adults who previously lived by themselves or their parents. The arrival of children changes the structure and dynamics of the newly formed family. These are all normal developmental events, but they can also lead to mental distress, physical problems, and social alienation.

Married adults are healthier than those in other nonmarried groups. Married

adults are least likely to experience health problems and least likely to engage in risky health behaviors with one exception: middle adulthood married men have the highest rate of overweight or obesity. Widowed, divorced, or separated adults are more likely to experience serious psychological distress than married adults. In a dysfunctional marriage, problematic eating behaviors increase health problems (Roberson et al., 2018).

The prevalence of physical inactivity in leisure time, current cigarette smoking, and heavier drinking of alcohol is higher in those who are widowed, divorced, separated, never married, or living with a partner (Schoenborn et al., 2018). Rates of separation or divorce are at least twice as high for those with almost any psychiatric disorder as for those without disorder.

Men and women are marrying later than in the 1990s. In 2019, the median age of men who marry for the first time was 30.1 and for women 28.3 years (Statista Research Department, 2021). Men and women who marry in the teen years have the highest probability of divorce, whereas individuals with a higher education are more likely to be married. The percentage of couples who cohabitate decreases as education increases (Lamidi et al., 2019).

There is an emerging trend for fewer women to marry and, at the same time, there is an increase in the percentage of women who cohabitate (Lamidi et al., 2019). There are an increasing number of women who never marry. The proportion of pregnancies occurring in women of at least 35 years of age has increased from 6.2% in 1980 to 22.3% in 2016 (Heazell et al., 2018).

Caring for Others

In 2019, 73.5 million children (younger than the age of 18 years) resided in the United States, up from 64 million in 1990. Most of these children (70%) lived with two parents and approximately 21% lived with only their mother, 4% lived with only their father, and another 3% lived in households with neither parent present. Within these numbers, there are further variations in ethnic groups. Seventy-eight percent of White, non-Hispanic, 70% of Hispanic, and 42% of Black children lived with two parents in 2015 (U.S. Census Bureau, 2019).

Whether functioning in a two-parent or single-parent home, parents who work out of the home must provide for the care and safety of their children during their absence. Childcare outside the home is often disproportionately expensive compared to income and often is not available for parents working evenings,

nights, holidays, or weekends and during periods of illness and other crises. Federal support to single-parent families is limited. Working parents could formerly rely on their own parents and other family members to assist with childcare, but today many parents have no family available locally or are also serving as caretakers to family members in addition to their children.

In fact, **informal caregivers**, unpaid individuals who provide care, are the largest source of long-term care services in the United States. It is estimated that more than 47.9 million people provide care to an adult or child, with about 41.8 million of these Americans providing unpaid care to an adult age 50 or older in the last 12 months. Although men are increasingly becoming more involved in caregiving, women comprise the majority and perform the more difficult tasks of caregiving. The duration of caregiving spans from less than a year to more than 40 years, with an average duration of 4.5 years (National Alliance for Caregiving, 2020).

Caregivers are under considerable stress and often neglect their physical and mental health needs. Caregivers also report higher levels of loneliness, anxiety and depressive symptoms, and other mental health problems than non-caregiving peers. In turn, altered physical and mental health reduces the quality, satisfaction, and ability to cope with daily stresses related to caregiving (National Alliance for Caregiving, 2020).

Unemployment

Employment is an important societal value and thus serves as a source of economic, social, and emotional stability and self-esteem. Young and middle-adulthood adults seek and maintain employment that maintains their lifestyle and provides for their children. In a society that is consumer driven, the ability to generate resources becomes critical. Yet shifts in the ownership and organizational structure of companies, downsizing, and the job market's ever-changing demands for workers with particular skills make employment stability questionable, both now and in the future. Career changes and the continuing necessity of training for new positions are now the norm.

In 2020, the United States began facing an economic recession resulting in the coronavirus disease 2019 (COVID-19) pandemic. The unemployment rate jumped to over 14% in spring and by mid 2020, the rate dropped to over 10%, up 3.7% a year earlier. The minority population was especially hit hard, with the

unemployment rate of Blacks or African Americans and Hispanics or Latinxs at over 18%. Generally, those with limited education and nonskilled workers remain at special risk for low wages and unemployment (U.S. Bureau of Labor Statistics, 2020).

COVID-19 put single mothers in an impossible situation. Low-income and single mothers often are employed in low-wage jobs, which disappeared. During the national shutdown of businesses, 28% of single mothers lost their jobs. Then as the restrictions on businesses eased with stay-at-home orders, single mothers were faced with returning to work or staying at home with their children who were no longer in school or daycare. Single mothers are another group at high risk for low wages and unemployment.

Within the cohort of unemployed workers, there are twice as many people with mental disorders. Of those with a mental illness who are working, many are underemployed; about 70% who hold college degrees earn less than \$10 per hour (NAMI, 2014; SAMSHA, 2014).

MENTAL DISORDERS IN YOUNG AND MIDDLE ADULTHOOD

The great majority of people experience their first diagnostic symptoms of mental illness during late adolescence or early adulthood. By far, the highest rates of mental disorder occur among young adults. Late-life onset of mental disorder (older than age 40 years) is relatively rare, with the exception of cognitive impairment, which typically occurs past the age of 70 years. Recent research suggests that 1 in 5 adults will experience a mental disorder in their lifetime and that within a year, 1 in 25 will experience serious mental illness in the United States (NAMI, 2020).

Changes in the biologic, psychological, and social domains can create a matrix of stress that may foster mental disorder. The vast majority of people with mental disorders do not come to the attention of the mental health system. In fact, fewer than half of those with mental disorders receive any kind of treatment from mental health professionals (Mental Health America, 2020).

RISK FACTORS FOR YOUNG AND MIDDLE

ADULTHOOD PSYCHOPATHOLOGY

Mental health promotion and illness prevention are driven by cultivating an awareness of personal risk factors for mental illness and modifying those that can be changed. Specific **risk factors**, or characteristics that increase the likelihood of developing a disorder, can contribute to poor mental health and influence the development of a mental disorder. Risk factors do not cause the disorder or problem and are not symptoms of the illness but are factors that influence the likelihood that the symptoms will appear. The existence of a risk factor does not always mean the person will get the disorder or disease; it just increases the chances. There are many different kinds of risk factors, including genetic, biologic, environmental, cultural, and occupational. Even gender is a risk factor for some disorders (e.g., more women experience depression than men) (see [Chapter 25](#)). In general, gender, age, unemployment, and lower education are risk factors associated with mental illness.

Biologic Risk Factors

The biologic functioning of young versus middle-aged adults is a contrast between optimally running physiologic systems and those showing definite signs of wear and inefficiency. Of course, there are wide variations in the health of the various systems within each stage, with some young adults more physiologically and functionally compromised than their middle adulthood counterparts. Most physical and mental systems have completed development by the time an individual reaches young adulthood. In general, the optimal health state of young adults begins to show changes around the age of 30 years. The perception of these physical changes often makes individuals aware of their aging process and may result in threats to bodily integrity and self-esteem. This section reviews the primary changes in the health of physiologic symptoms and possible mental health implications.

Skin

The most obvious change in physical appearance starts with the skin. Although the young adult's skin is smooth and taut, by late young adulthood, the skin

begins to lose moisture and tone, and wrinkles develop. Self-esteem issues can erupt as the skin ages, especially for women.

Cardiovascular and Respiratory Systems

Maximum cardiac output is reached between 20 and 30 years of age. Thereafter, blood pressure and cholesterol levels gradually increase. Although men are especially prone to cardiovascular disease in middle age because of testosterone levels, women are not exempt from risk of heart disease. In a parallel manner, respiratory function also decreases with age. After the age of 30 years, maximum breathing capacity slowly decreases and may be reduced up to 75% compared with during young adulthood. Such changes are compounded if the individual smoked throughout adulthood. Alterations in cardiac and respiratory efficiency may result in limited energy for daily tasks and preference for lower activity levels, which makes exercise less of an enjoyable activity (Hart & Zernicke, 2020).

Sensory Function

Sensory functions are also compromised as an individual moves from young into middle adulthood. Although the visual sense is at its peak in early young adulthood, the lenses of the eyes gradually lose their elasticity around the age of 30 years, and corrective lenses may be necessary. Such changes may result in issues regarding physical appearance that may affect self-esteem. Hearing is optimal in young adulthood, but middle age brings changes in the bones of the inner ear and auditory nerve, resulting in the gradual inability to hear high-pitched tones and detect certain consonants. Such alterations in hearing may also present issues related to body integrity.

Neurologic System

In middle age, brain structural changes are minimal. Although neurons are gradually being lost, changes in cognition are not evident. There may be some

slowing of speed of reflexes because of small changes in nerve conduction speed during middle age.

Basal Metabolic Rate

Basal metabolic rate is at maximum functional capacity at the age of 30 years and then gradually decreases at a rate of 2% per decade, related to a gradual loss in highly physiologically active muscle mass. The ratio of fat tissue to lean body mass gradually increases, which may result in weight gain if calories are not restricted. There is currently an epidemic of obesity within the United States because of poor nutrition and low activity levels. Weight gain also raises concerns about changes in physical attractiveness, especially in women. It is also related to decreased cardiac and respiratory efficiency, which makes exercise less of a preferred activity (Patnode et al., 2017).

Sexual and Reproductive Functioning

Concerns about changing physical appearance may also be tied to reactions to changes in sexual functioning. In middle-aged men, testosterone production decreases, resulting in a lower sex drive, more time needed to achieve erection, and production of fewer sperm cells. Men whose sense of self was dependent on the level of sexual functioning typical of young adulthood may experience anxiety over such changes. Diminishing estrogen levels in middle age in women result in the cessation of menses and capacity for pregnancy. The beginning of menopause may bring unpleasant symptoms such as hot flashes, night sweats, fatigue, and nausea. However, most women experience menopause as a relief from menses, fluctuating hormone levels, and the possibility of pregnancy. Women whose view of self was based on sexual characteristics may also be prone to anxiety because of these changes.

Psychosocial Risk Factors

Any of the common challenges of adulthood previously discussed such as

unemployment, changing family structure, and caregiving may serve as risks factors for mental disorders. These more general problems reveal underlying risk factors that have shown to be common in the development of mental disorders. Also, risk factors rarely occur in isolation but tend to cluster because one may bring about another, and they influence each other.

Age

The majority of mental disorders occur among young adults and appear to be less common with increasing age. The first symptoms may occur in childhood but are usually evident in late adolescence and early middle adulthood. Such symptoms may be partially tied to the increasing demands for independence and social responsibility that Western society places on developing individuals. As some adults get older, they may experience decreasing stress because of learning to cope more efficiently.

Marital Status

Individuals who are happily married experience higher rates of both physical and mental health compared with those who are single, separated, or divorced. Marriage may serve as a general marker for psychological health and the ability to connect with larger social networks. In contrast, an unhappy marriage can have negative health effects. Unmarried individuals may experience positive physical and mental health especially if they are not isolated from others and have support from a larger social system (Pandey et al., 2019; Robles, 2014).

Unemployment and Other Job Stresses

In this consumer-oriented society, economic stability is a major value. Unemployment is a larger indicator of such socioeconomically related variables such as those experiencing poverty, lack of education, and the ability to obtain economic power within the larger social system. This creates an environment of stress that may contribute to the development of mental disorder or may indicate

the negative effect that mental disorder has had on obtaining the education and independence necessary for obtaining job security and advancement. Employment rates for individuals with mental illnesses are notoriously low. Employment declined from 23% in 2003 to 17.8% in 2012. Most adults with a mental disorder want to work and approximately 6 out of 10 can work with the proper supports (NAMI, 2014).

Conversely, employment has its own set of stresses. Many people with low-paying jobs work two jobs, often going directly from one job to another. Shift work causes changes in circadian rhythms and sleep patterns, leading to an increase in stress. Interpersonal problems with coworkers can lead to emotional distress. Challenges even arise related to the different learning styles and career expectations of workers of different ages and backgrounds or who are reentering the workforce.

Gender

Women come to the attention of the mental health system because of their greater awareness of health issues and willingness to seek interventions. However, women also differ in the types of mental disorders that they show. Whereas women are more prone to anxiety and depression, men tend to show problems with impulse control that result in alcohol use disorder and substance use disorder.

History of Child Abuse

Being abused as a child increases the risk of a mental disorder as an adult. Data from a national survey indicated that there are long-term consequences of early childhood abuse. Reported emotional abuse was associated with lower personal control, which in turn leads to lower health ratings (Li et al., 2016).

Prior Mental Disorder

Mental illness tends to be a chronic disorder with symptoms manifesting fairly

early in life. Research has shown that mental illness arising in childhood and adolescence predicts further disorder in later years. Because most mental disorders are never cured, the existence of prior symptoms or full-blown disorder is a risk for mental illness at later periods in life. Increased stress provides the ground for the current emergence of symptoms of mental disorders that may have appeared to be in remission (Li et al., 2016).

Coping

Although the quality of coping is important in the reduction of stress, little is known about the continuity and changes in coping styles over the life span. Because past behavior is the best predictor of future behavior, it would appear that coping styles used in the past would be repeated in the present time. The quality of such coping would determine how well stress is handled in the present and sets the stage for continued positive outcomes or more problems in the future.

There is an absence of epidemiologic studies that directly compare adult life stages according to mental health variables such as stress and coping. An exception is the Midlife Development in the United States (MIDUS) Study, which included more than 7,000 subjects between 25 and 74 years of age and those at midlife (defined as 40–60 years). The results of this study that compared young and middle-aged adults suggest that the process of coping improves in quality as life and satisfaction with life. A longitudinal follow-up of MIDUS respondents occurred over 2002 to 2006 and 2011 to 2016. The purposes of the follow-up were to repeat the assessments obtained in the original study and to expand into other areas of biologic and neurologic assessments. There are hundreds of research publications generated from this study. See [Box 17.1](#) for an example.

Well-Being

Mental, physical, and social well-being is an indicator of positive functioning. As part of the Behavioral Risk Factor Surveillance System, a national survey that monitors behaviors that place individuals at risk for health problems and

mental, physical, and social well-being was reported in three states. Most adults were satisfied with their work, neighborhood, and education but well-being varied by marital status, health, chronic conditions, and disability. People with disabilities, current smokers, and those who were unemployed or unable to work had low mental well-being (Kobau et al., 2013). In a related study, the prevalence of minor and major depression among pregnant women in the United States was compared. Major depression was not greater among pregnant women than nonpregnant women, but the prevalence of minor depression was greater among pregnant women (Ashley et al., 2015).

BOX 17.1

Adverse Childhood Experiences and Adult Coping Strategies

Sheffler, J. L., Piazza, J. R., Quinn, J. M., Sachs-Ericsson, N. J., & Stanley, I. H. (2019). Adverse childhood experiences and coping strategies: Identifying pathways to resiliency in adulthood. *Anxiety, Stress, and Coping*, 32(5), 594–609. <https://doi.org/10.1080/10615806.2019.1638699>

THE QUESTION: Do coping strategies facilitate the link between adverse childhood experiences (ACEs) and adult psychiatric and physical health outcomes?

METHODS: This study included wave I (n = 7,108), wave II (N = 4,963), and wave III (N = 3,294) of the MIDUS survey. Seven adverse events were related to coping strategies at the 20-year follow-up.

FINDINGS: Wave I adverse ACEs were associated with worse psychiatric and physical health outcomes. At Wave II, the adverse childhood events were associated with greater use of avoidant emotion-focused coping and lower use of problem-focused strategies.

IMPLICATIONS FOR NURSING: Learning coping strategies may be important for promoting mental and physical health in children who have had ACEs.

Lack of Health Promotion Behaviors

People with mental disorders in young adulthood and middle age appear to lack basic health promotion behaviors. This lack results in high rates of physical illness and premature mortality compared with the general population. This includes low levels of awareness about physical and mental health issues, smoking, poor quality diets, lack of exercise, lack of leisure activities and contact with friends, negative attitudes toward help seeking, and stigma associated with mental health problems (Ashdown-Franks et al., 2020).

NCLEXNOTE People with mental disorders frequently neglect their physical health and have premature mortality. Assessment of physical health and health-promoting activities is important in the care of people with mental disorders because of their high rate of smoking, lack of physical activity, and resistance to seeking help for physical concerns.

Parenting Stress

Young adults often find that the addition of children to the family, particularly the birth of the second child, tends to insulate the nuclear family from larger social networks. The responsibilities and time constraints involved in rearing small children may limit the couple's worldview to the home, and definitions of self may be constricted to the activities of the nuclear family. However, as children grow and create their own lives, the social connectedness of the parents tends to expand. By middle age, couples may anticipate the emancipation of their children and may entertain more options for socializing with other people.

Factors Associated with Suicide

Suicidal ideation and suicide were serious public health problems in the United States before the COVID-19 pandemic (see [Chapter 22](#)). The mental health challenges cause the disease, and mitigation activities such as physical distancing and stay-at-home orders made the problems worse. In a large study during June 2020, 5,412 adults completed a web-based survey related to mental health conditions associated with COVID-19. Approximately twice as many reported serious considerations of suicide during the last 30 days compared with adults answering this same question in the United States in 2018. The percentage of respondents who reported having seriously considered suicide in the 30 days before completing the survey (10.7%) was significantly higher among respondents aged 18 to 24 years (25.5%) and minority racial/ethnic groups (Hispanic respondents [18.6%], non-Hispanic Black respondents [15.1%], self-reported unpaid caregivers for adults [30.7%], and essential workers [21.7%]) (Czeisler et al., 2020).

PROTECTIVE FACTORS

In contrast to risk factors, **protective factors** are characteristics that reduce the probability that a person will develop a mental health disorder or problem or decrease the severity of existing problems. Common protective factors exist in multiple contexts—families, communities, and society. All of these contexts should be considered when promoting mental health. For example, parental involvement can help combat drug abuse in their children, but a strong school policy is also needed. In addition, other community resources must be used to support the drug-free community environment. Targeting only one context is unlikely to make a lasting impact.

INTERVENTION APPROACHES

Many nursing interventions are effective in helping young and middle-aged adults achieve greater mental health. Whereas some are geared toward helping adults cope with the challenges typical of this period of life, others are more specifically designed toward preventing depression and suicide. Another aspect of intervention is helping adults overcome societal pressures that might prevent them from seeking care in the first place.

Mental Health Promotion

The psychiatric mental health nurse supports the young and middle-aged adult through the developmental journey of life. Stresses associated with balancing the psychosocial demands and the adjustment to changes in the biologic, psychological, and social domains can be overwhelming. Validation and education are important interventions in helping these individuals cope with these changes (see [Chapter 18](#)).

A person's mental health can be challenged by a variety of factors: Biologic changes or illnesses, psychological pressures, and interpersonal tensions are only a few. Developing coping strategies to eliminate or reduce the impact of these potentially destructive factors is a part of normal growth and development. In

addition, sustaining positive health behaviors such as relaxation, proper nutrition, adequate sleep, regular exercise, and forming a network of trusting relationships can support one's mental health. Mental health promotion focuses on increasing the individual's physical, mental, emotional, and social competencies to increase well-being and actualize potential.

Social Support During Life Transitions

Young and middle-aged adults are prone to many life transitions: entrance into the workforce, job loss, career change, separation, divorce, the birth of children and their eventual leaving home, and changes in health status. Middle-aged adults are also subject to watching their parents' age and possibly lose independence. Both young and middle adults can benefit from education about coping with the stresses involved with such transitions, linking with sources of social support, and anticipating the changes in role and adjustment.

Lifestyle Support

Although health may be at its maximum during the young adult years, changes in bodily appearance and function become evident by the age of 30 years and become more pronounced as middle age begins. Although such changes are inevitable, their magnitude can be tempered by health promotion activities such as attention to regular exercise, good nutrition, adequate sleep, health screening, relaxation, leisure, and other forms of stress management. The young adult years are times of learning positive coping strategies for the stresses inherent to personal, marital, family, and occupational life. Such learning can be enhanced by a social support network consisting of people who are currently undergoing such stresses as well as older people who have the perspective and experience in handling these domains of life. These networks can be informal, such as regular contact with a circle of friends, or more formal, such as support groups sponsored by social, occupational, and religious organizations. A sense of belonging and availability of social support is important for the maintenance of health and recovery from illness of all kinds.

Self-Care Enhancement

The latter part of young adulthood and middle age are times when chronic illnesses such as hypertension, heart disease, and arthritis may become evident. Symptoms of mental disorders may have arisen earlier in life but require continuous care because of their chronic and episodic nature. It is important for both young and middle-aged adults to be educated about the physiologic aspects of such disorders, the advances in medications used in treating them, possible side effects, the importance of medication adherence, lifestyle changes that can be instituted to control such disorders, and the possible use of complementary healing methods (e.g., massage, meditation). Such strategies require a good relationship with a health care provider as well as initiative from individuals to contributing to their own care through seeking and evaluating information available in the media, on the Internet, or from advocacy groups.

Prevention of Depression and Suicide

Suicide is the 10th leading cause of death for all ages in the United States but ranks as the 2nd leading cause of death for people of ages 10 to 34 and the 4th leading cause for people of ages 35 to 54. The suicide rate is consistently higher for males than females. Suicide rates are increasing in most rural counties for both males and females (Hedegaard et al., 2020).

Symptoms of most psychiatric disorders have made their appearance by the time an individual enters young adulthood. In particular, mood disorders may first arise during the young adult years and continue through middle age and older adulthood. Because depression is a significant precipitating factor for suicide, early detection and intervention are critical for managing mood disorders and preventing suicide. Routine screening for depression and associated substance abuse is common in primary care settings.

Reducing the Stigma of Mental Health Treatment

Although mental disorders are common within the community and the rate of treatment has risen over the past 20 years, more than half of people do not

receive mental health treatment of any kind. Part of this lack of attention is certainly because of the lack of available treatment in many communities (e.g., rural areas), but another major factor is the stigma that continues to be associated with mental illness and seeking help for mental health problems. Organizations such as the National Alliance on Mental Illness have spearheaded the movement toward viewing mental disorders as biologically based and devoid of moral implications, putting them on par with physical disorders. National Alliance on Mental Illness is an important organization for obtaining information, support, and referrals for treatment for individuals with mental disorders as well as their families.

The Future of Mental Health for Young and Middle-Aged Adults

Young adulthood and middle age can be some of the most productive periods in life. They can also be the most stressful and debilitating because of the rapid rate of social change and economic instability that society is currently experiencing. The division of adulthood into young- and middle-aged stages and the interest in adult development have paved the way for examining the challenges unique to these stages, in which individuals spend the majority of their lives. More needs to be known about the stresses of these stages, the ways that individuals cope, the changes that bring about increased life satisfaction, and the ways in which nurses can support adaptation and ensure health promotion. Such health-promoting interventions may serve as the foundation for future mental health.

Although more is known about childhood and older adults because of the more dramatic and time-dependent aspects of their development, the more subtle changes of adulthood also deserve consideration. Development does not end at childhood, and more needs to be known about the manner in which young adults progress within their lives and achieve the satisfaction reported with middle age.

Research also needs to examine the variables that promote and protect mental health as well as understanding risk factors. Researchers and clinicians often equate promotive or protective factors with the absence of risk factors. This is tantamount to equating health with the absence of illness. Models of thriving and flourishing in response to life's challenges have been proposed by theorists as a more appropriate model for mental health promotion rather than adequate functioning or the lack of criteria for a psychiatric disorder. Those who flourish

do not merely lack psychiatric disorders; they also have lower risk for cardiovascular disease and other chronic physical illnesses, fewer health-related limitations, lower health care utilization, fewer missed days of work, and high resilience and intimacy. The adoption of such positive models has implications not only for prevention of mental illness but also for more proactive interventions that ensure continued wellness that progresses into older adulthood.

SUMMARY OF KEY POINTS

- Western families have achieved unprecedented economic stability that provides for long periods of development and a range of choices in lifestyle.
- The periods of young and middle adulthood do not exist in less developed countries; a brief childhood progresses quickly into old age.
- Western society has recently shown greater tolerance for the timing of life events such as education, marriage, and childrearing.
- The periods of young and middle adulthood are characterized by changes in family structure caused by children leaving and returning home, marriage, and divorce.
- Caregiving for both children and older parents is a potential stress faced by both young and middle-aged adults.
- Unemployment is a growing common problem in adulthood, particularly for single mothers and African Americans.
- Mental disorders are most common in young adults, with the first symptoms evident in late adolescence and young adulthood, with the exception of cognitive impairment.
- As individuals progress from young to middle adulthood, they experience changes from optimally running physiologic systems to those showing wear and inefficiency.
- Psychosocial risk factors for mental disorders include age, marital status,

unemployment and job stresses, gender, prior mental disorder, coping, lack of health promotion behaviors, parenting stress, and factors associated with suicide.

- Despite decreases in the efficiency of physiologic functioning, young and middle-aged adults often lack health-promoting behaviors, especially if they have mental disorders.
- Suicide is a growing problem in young and middle-aged adulthood, especially in the light of the recent COVID-19 pandemic and economic downturns. It requires early detection and treatment.
- Social support and stress management are important in helping people to cope with the stresses involved in life transitions.
- Fewer than half of individuals receive treatment for their mental health issues, and stigma remains toward those experiencing problems.
- Mental health promotion in adulthood needs to embrace positive models of people who flourish in life rather than those who lack mental illness. Little is known about the factors that promote or protect mental health.

CRITICAL THINKING CHALLENGES

1. What are your assumptions about the psychosocial tasks that should be accomplished by an individual in American society who is young versus middle aged? Describe the challenges that each age group faces in terms of education, marriage, career, children, financial stability, and health and the expected outcomes for each of these challenges. Then compare your answers with another person's. In which areas do you agree and disagree? Why do the perceptions of the tasks of young and middle-aged adulthood differ from person to person?
2. Describe the modifiable risk factors for mental disorders for young and middle-aged adults and suggest mental health promotion activities that can be used to address these risk factors.
3. What factors do you think are protective or promotive of mental health? How do physical health and mental health overlap? What kinds of interventions may promote both physical and mental health?

Movie Viewing Guides

The Kids Are All Right: 2010. This is a film about a lesbian couple and their adolescent daughter and son who were both conceived from the same anonymous donor via artificial insemination. The daughter, who is preparing to leave home for college, decides to initiate contact with her biologic father. The introduction of the father, although pleasant at first, ultimately reveals the strains in the family's relationships and functioning. This film illustrates the children negotiating the identity tasks of adolescence and ambivalently assuming initial responsibilities of young adulthood. The parents mirror their children's struggles in terms of renegotiating the roles played in their marriage, their lesbian identities, the level of independence given to their children, and acknowledging the imminent "empty nest."

VIEWING POINTS: Identify the life transitions faced by each of the family members in the film. How does each member cope with the stresses they are experiencing? How are the developmental issues the parents are facing similar to their children's? How did the entrance of the father highlight the conflicts and ultimately change the dynamics in this family?

Mental Health Promotion for Older Adults

Mary Ann Boyd

KEYCONCEPTS

- late adulthood
- cognitive health

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Describe developmental processes supporting mental health in late adulthood.
2. Describe neurobiologic and psychosocial changes that impact successful aging.
3. Identify risk factors that challenge mental health status.
4. Identify protective factors in the mental health promotion of older adults.
5. Discuss mental health prevention and promotion interventions with older adults.

KEY TERMS

- Bridge employment
- Cognitive aging
- Cognitive reserve
- Crystallized intelligence
- Older adult mistreatment
- Fluid intelligence
- Functional status
- Gerotranscendence
- Middle–old
- Old–old
- Polypharmacy • Resilience
- Social isolation
- Working memory
- Young–old

INTRODUCTION

The number and proportion of older adults in the United States is rapidly increasing. By 2050, it is expected that Americans aged 65 and older will number nearly 83.7 million, more than double the number of older adults in the United States in 2012. The reason for the rapid growth in the aging population is that Americans are living longer lives (Arias et al., 2021).

More than a quarter of all Americans and two of three older Americans have multiple chronic conditions. Ninety percent of the U.S. health care expenditures are for people with chronic and mental health conditions (CDC, 2020a). Older adults are at somewhat greater risk than younger age groups for the development

or recurrence of mental health problems. One in four older adults have a significant mental disorder, with depression, anxiety disorders, and dementia being among the most common (McCombe et al., 2018). There has been a significant increase in use of antianxiety, sedative, and hypnotic medications in community-dwelling older adults as well as an increase in use of antidepressants in this group. Even with a high usage of psychotropic medications, depression often remains untreated in this population.

Yet, despite the high prevalence of psychiatric disorders and mental health problems in later life, older people remain vastly underserved by the current mental health system. This chapter explains the effects of aging on mental health and identifies risks and protective factors related to the mental health problems of older adults.

OLDER ADULT MENTAL HEALTH

Changing needs and personal development characterize older adulthood. This stage of life can be conceptualized in roughly three stages: **young-old** (ages 65 to 74 years), **middle-old** (ages 75 to 84 years), and **old-old** (age 85 years and older). The needs are different in the young-old than in the old-old. Generally, the young-old are challenged to develop new roles after retirement. This group of individuals may need programs and services that help them find meaningful activities. The old-old group tends to need supportive and protective services. However, the aging process is very individualized. Some young-old need supportive services and some in the old-old group are just beginning retirement (Maltais et al., 2019).

KEYCONCEPT Late adulthood can be divided into three chronologic groups: young-old, middle-old, and old-old.

The quality of the journey through older adulthood depends on many factors including biologic changes and psychosocial situations. When older adults retire from their lifelong work, they are challenged to establish a new meaning in life. There are now opportunities to do the things, such as traveling and visiting friends, that were impossible when work and family responsibilities took precedence. If there are health issues, financial limitations, or family problems, the person may not be able to pursue retirement opportunities.

The individual's perception of aging also can impact late adulthood. For example, as once-dependent children grow into adulthood and become parents themselves, they no longer require close attention. No longer having dependent children is viewed positively by some who have more time to pursue personal interests and negatively by others who feel lonely and abandoned. The nurse can be instrumental in helping older adults consider the potential growth opportunities during this time.

COMMON CHALLENGES IN OLDER ADULTHOOD

Changes in vital biologic structures and processes occur gradually over decades and become evident in late adulthood. However, many older adults integrate profound decrements in physical capacity without significantly affecting their ability to function under normal conditions. It is only when functional reserves are needed, such as during an infection, that the absence of these reserves may be observed. Changes in health status, for example, can lead to loss in physical functioning and independence, which in turn can result in an unplanned change in residence. The risk of depression is increased as functional limitation increases and perceived physical health declines (Gouveia et al., 2017).

Physical Changes

Many physical changes occur in older adults. Typically, body fat increases (18% to 36% in men; 33% to 48% in women), total body water decreases (10% to 15%), and muscle mass decreases. In the renal system, there is a predictable decline in glomerular filtration and tubular secretion. Although less efficient, the renal system without disease or injury can function adequately throughout late adulthood (Saxon et al., 2015). Liver function may be reduced because of decreases in blood flow and enzyme activity, resulting in increased blood and tissue concentrations of medications as well as half-life prolongation. Also, fat-soluble drugs may become sequestered in fatty tissue, rather than remaining in the circulating plasma, increasing the risk for drug accumulation and toxicity (see [Chapter 11](#)). Age-related changes in the brain are highly individual. For

example, cortical thickness and anterior midcingulate cortex in some older adults (60 to 80 years) are indistinguishable from those in younger adults (Sun et al., 2016). For others, there may be a loss of neurons and a general atrophy of the brain (Saxon et al., 2015). Any of these changes over time can compromise the physiologic reserves to manage the everyday stresses of life.

Sensory Changes

All five senses gradually decline in acuity with age, usually beginning in the fourth and fifth decades of life, but these changes do not limit activity until the seventh and eight decades (Saxon et al., 2015). Visual and auditory losses can significantly impact independence and self-mastery. Taste, touch, and smell undergo a uniform dulling although the rate of decline is highly variable among individuals. Sensory decline is important to consider when assessing psychiatrically ill older adults because diminished senses may affect information processing, potentially affecting interpretation of standard mental status examinations. For example, patients who do not reveal hearing difficulty may be evaluated instead for dementia or depression.

Sexuality

Interest in and enjoyment of sexual activities can continue until one's death despite physical changes that affect sexual functioning. Health, a desire to remain sexually active, access to a partner, and a conducive environment contribute to positive sexual experiences. Physiologic changes in women related to sexual functioning include decreasing estrogen levels, alterations in the structural integrity of the vagina (e.g., decreased blood flow, decreased flexibility, diminished lubrication, and diminished response during orgasm), and decreased breast engorgement during arousal (Saxon et al., 2015). Physiologic changes in men include a decline in testosterone production, increased time to achieve erection, less firm erections, decreased urgency for ejaculation, decreased sperm production, and a longer refractory period (i.e., the amount of time before the man can achieve another erection). Problems with sexual performance in aging men are usually centered around erectile dysfunction,

which in turn, affects self-esteem (Saxon et al., 2015).

The issue of sexuality in older adults is more complicated than just the physiologic changes. Sexual activity declines with age, with women less likely than men to report being sexually active, but a large number of men and women remain sexually active into their eighth and ninth decades (Macleod et al., 2020). Access to a conducive environment for sexual expression may be hindered if an older adult resides with an adult child or in a nursing home. Stigma associated with sexual activity in later life is also perpetuated by young adults' negative attitudes toward late-life sexuality and further contributes to lack of acceptance that sexual feelings and behaviors are normal at all ages. Lack of acceptance by others, particularly family members, and lack of privacy further contribute to a sense of isolation, loneliness, and poor social support, which are all associated with risks for depression (Srinivasan et al., 2019).

Psychological Changes

Cognitive Health

Cognition includes several mental functions such as attention, thinking, understanding, learning, remembering, solving problems, and making decisions. Cognitive health, the maintenance of optimal cognitive function with age, is multidimensional and relies on a number of interrelated abilities that depend on brain anatomy and physiology. Many cognitive abilities (e.g., knowledge accumulated over a lifetime) are preserved or even enhanced during aging. Additionally, even though there are areas of cognitive decline beginning in middle adulthood, older adults can successfully use compensatory strategies to offset these changes and have a wealth of knowledge, skills, and experiences that younger adults may not have (Lövdén et al., 2020).

KEYCONCEPT **Cognitive health** is the maintenance of optimal cognitive function with age.

Cognitive aging is a process of gradual, ongoing, yet highly variable changes in cognitive functions that occur as people get older. Cognitive aging is a lifelong process beginning in utero. Normal aging does not impair consciousness, alertness, or attention. Health and environmental factors over a life span influence cognitive aging. Individual factors, including genetics,

culture, medical comorbidities, acute illness, customary activity levels, socioeconomic status, education, and personality may modify the development or expression of age-related changes in cognition (IOM, 2015).

Mental Processing Speed and Reaction

Mental processing speed and reaction gradually decline in aging. Generally, it takes longer for older people to process information and give a response, which can lead to problems in reaction times (driving) and interactions with others. These changes may influence other cognitive operations such as working memory, speech processing, and attention. A person's ability to remember spoken word, attend to important information, or perform tasks may also be affected. Decline in processing speed may be offset by experience. For example, if older adults continue to engage in complex activities such as maintaining computer skills, they may not experience a significant decline in processing information. Communication with older adults requires paying special attention to verbal interactions and environmental influences. Hurrying older adults to answer questions may interfere with their ability to provide the correct answer (Saxon et al., 2015). [Box 18.1](#) highlights many of the considerations necessary when interacting with older adults.

BOX 18.1

Communicating with Older Adults

- Focus the person's attention on the exchange of communication; the older adult may need extra time to begin to process information.
- Face the person when speaking to them.
- Minimize distractions in the room, including other people, objects in your hands, noise, and other activities.
- Reduce glare from room lighting by dimming too bright lights. Conversely, avoid sitting in shadows.
- Speak slowly and clearly. Older adults may depend on lip reading, so ensure that the individual can see you. Speak loudly, but do not shout.
- Use short, simple sentences and be prepared to repeat or revise what you have said.
- Limit the number of topics discussed at one time to prevent information overload.
- Ask one question at a time to minimize confusion. Allow plenty of time for the person to answer and express ideas.
- Frequently summarize the important points of the conversation to improve understanding and comprehension.
- Avoid the urge to finish sentences.
- Consider factors such as fatigue and discomfort in structuring the communication.

- If the communication exchange is going poorly, postpone it for another time.

Memory

Older adults often worry about changes in memory as they age. Memory problems in later life are believed to result from encoding or retrieval problems (or both). There are many types of memory (measured by neuropsychologic tests); some remain stable and others decline. **Working memory**, the ability to temporarily hold information in one's mind while it is processed, is central to many functions (see [Chapter 8](#)), such as remembering to take medication, processing language, solving problems, making decisions, and learning. Generally, working memory declines with age, especially for complex tasks. Despite these declines, performance of well-learned tasks often shows little declines. For example, there is little evidence that older workers are any less productive than younger workers. In most day-to-day tasks, older adults perform very well (IOM, 2015).

Other factors associated with memory changes include a lack of perceived relevance, sensory problems, not paying attention, a general failure to link the “to be remembered” information to existing knowledge through association, and a lack of using repetition to strengthen memory. The learning abilities of older people may be more selective, requiring motivation (“How important is this information?”), depend on meaningful content (“Why do I need to know this?”), and be related to familiarity with the idea or content. Level of education needs to be considered in evaluating responses on mental status examinations because lack of education may account for poor performance.

Although a decline in memory efficiency may be frustrating for the older individual, it does not necessarily hamper their ability to function daily (IOM, 2015). Threats to memory include medications, depression (impairs concentration and attention), poor nutrition, infection, heart and lung disease (lack of oxygen), thyroid problems (can cause symptoms of depression or confusion that mimic memory loss), alcohol use, and sensory loss (interferes with perception). However, it is important not to confuse memory decline with deficits in memory storage, such as those that are seen in dementias (see [Chapter 38](#)).

Intelligence

Intelligence includes both **crystallized intelligence**, knowledge such as language skills or knowledge about a particular topic, and fluid intelligence, that is, processing current or new information. **Fluid intelligence** involves thinking logically and solving problems. Crystallized intelligence remains fairly stable with modest declines in later life. Declines in fluid intelligence begin earlier and are more gradual throughout the life span (IOM, 2015). Similar to other cognitive aspects, intelligence is impacted by other factors, including the environment, social context, knowledge, prior experience, health status, the demands of the task, and support.

Cognitive Reserve

The variability in cognitive aging can partially be explained by the concept of **cognitive reserve**, the resistance to decline in functioning of the brain. Factors that contribute to cognitive reserve include education, occupational attainment, physical activity, and engagement in intellectual and social activities. A deficit in early-life cognitive reserve is often related to socioeconomic status. Staying physically fit and maintaining an active social network can have positive effects in older adults (Bettcher et al., 2019; Lövdén, 2020).

Personality

Personalities and personality traits are generally believed to be stable throughout the life span. Some personality traits are associated with longevity, such as conscientiousness, responsibility, self-control, and traditionalism. Personality traits, such as extroversion, openness to experience, agreeableness, and conscientiousness, are related to successful aging. People who are assessed with low conscientiousness (low self-esteem, acting spontaneously without planning, showing little persistence in pursuing long-term goals, and not being driven by obligations of duty and responsibility) have a higher mortality rate than those with an average sense of conscientiousness. Characteristics of low conscientiousness may lead to unhealthy life choices and risk-taking behavior. Even though we generally believe that personalities are formed by the age of 30 years, evidence shows that personality traits are shaped by the environment and social experiences throughout life. Occupational and romantic experiences and

other major life events influence the expression of personality traits in all age groups (Jokela, et al., 2020).

Development

Late-life adult developmental phenomena are not well defined. Early developmental theorists viewed older adults as having the same psychological and social needs as when they were younger. They believed that as the aging person gave up their roles as employee and parent, the individual should replace the role losses with new roles and increase social interaction (Havighurst, 1961). The Disengagement Theory is similar but proposed that the aging individual and society mutually withdraw from each other to prepare the individual for an eventual exit from society (Cumming & Henry, 1960). Later, Erik Erikson identified “integrity versus despair” as a developmental task specific to late adulthood (Erikson & Erikson, 1997). He proposed that the primary task of the older adult is to reflect on their past experiences. If the individual is satisfied with their life, this eighth stage is resolved, and the person attains wisdom and acceptance of death.

Unlike the earlier theories, the Gerotranscendence Theory describes **gerotranscendence** as the continuation or progression toward maturation and shifting from a materialistic and pragmatic view of the world to a more cosmic view. The individual may experience personal growth in dimensions such as spirituality and inner strength with an emphasis on the meaning of life and making positive use of solitude (Tornstam, 2005). The concept of gerotranscendence may be used in establishing health promotion interventions. Gerotranscendence is also congruent with more recent research about mental health in late adulthood, which is more optimistic and addresses successful aging. This approach focuses on generation awareness, awareness of aging, the big picture of life, and a need for solitude (Braam et al., 2016; Lee et al., 2020). See [Box 18.2](#) for one study focusing on enhancing the perception of gerotranscendence.

Emotional Health

Although personality is fairly stable across adulthood, emotional changes are small but generally positive. Aging adults tend to become more emotionally stable, more agreeable, and more conscientious, with a higher level of well-being. These positive changes are thought to be related to the development of better emotional regulation because of life experiences and involvement in meaningful activities, networks, and goals. Threats to emotional and physical well-being include limitations in daily activities, physical impairments, grief following loss of loved ones, caregiving or challenging living situations, or untreated mental illness such as depression and substance abuse.

BOX 18.2

Gerotranscendence: Perception and Depression

Shu-Chuan, Chen, Moyle, W., & Jones, C. (2019). *Feasibility and effect of a multidimensional support program to improve gerotranscendence perception and depression for older adults: A pragmatic cluster-randomized control study*. *Research in Gerontological Nursing*, 12(3), 148–158. <https://doi-org.libproxy.siu.edu/10.3928/19404921-20190212-01>

THE QUESTION: Is it feasible to improve gerotranscendence and reduce depression in community-dwelling older adults through providing a multidimensional support program (MSP)?

METHODS: Using a cluster-randomized control trial design, four sites (98 participants) were randomly assigned to a MSP or control group.

FINDINGS: The MSP was found to significantly enhance the perception of gerotranscendence in older adults but not their level of depression.

IMPLICATIONS FOR NURSING: This study demonstrated that the MSP is a feasible and effective program to improve perception of gerotranscendence and may potentially lead to positive psychological well-being for older adults.

Perception of Time

Older adults often comment that time seems to go faster than when they were younger. Experts have yet to agree on an explanation for this experience, but there are several factors that contribute to this change in time perception. The lives of older adults tend to be more stable than their younger counterparts as months, weeks, and years unfold with fewer life changes that demarcate periods of time. Life transitions of younger persons are often dramatically different from each other, such as children growing up and leaving home, job changes, and

relocation. Aging adults have less time in life than younger people. Younger persons often plan for their future, whereas time for older adults is limited. Thus, the present is the older adult's future, whereas a younger person prepares for a different future than their present life (Löckenhoff & Rutt, 2017; Rutt & Löckenhoff, 2016).

Social Changes

Functional Status

Functional status, the extent to which a person can independently carry out personal care, home management, and social functions in everyday life in a way that has meaning and purpose, often changes during the later years. Estimates of the prevalence of functional dependency vary, but in general, studies show that difficulty in performing activities of daily living and instrumental activities of daily living increases with advancing age and that cognitive impairment significantly predicts functional decline (Cornelis et al., 2019). It is important to remember that most older adults live in the community and perceive that they are aging well despite chronic illnesses and some physical disability. A sense of control and self-efficacy contributes to an older person's sense of self-mastery despite limitations.

Retirement

Research shows an association between successful aging and a happy retirement. The ability to adapt to change and remain engaged and involved in life and social networks contributes to the successful negotiation of the retirement transition. Voluntary retirement is associated with postretirement well-being. For many, **bridge employment** (paid work for those receiving a pension) alleviates the negative consequences of retirement for those who are forced to retire involuntarily (Carlstedt et al., 2018). On the other hand, changing roles and circumstances can cause stress and contribute to poorer mental health (Voss et al., 2020).

Financial concerns certainly impact one's adjustment to retirement. Social Security Annuity continues to provide the largest single source of income for

older adults, but retirement income security now often requires earnings from working in later life (Quinn & Cahill, 2016). The traditional “three-legged stool” on which retirement rests—Social Security, pensions, and savings and investments—disproportionately excludes some groups, such as people of color, LGBTQIA (Lesbian, Gay, Bisexual, Transgender, Questioning, Intersex, Asexual) members, women, and immigrants who have faced barriers to education, health, a stable work history, or financial stability. Many no longer have pensions or savings to sustain them in retirement (Tamborini & Kim, 2020).

Economic downturns have significant implications in terms of personal financial concerns; there is increased competition for jobs as well as a potential delay in retirement. Although mandatory retirement is becoming a thing of the past, older workers may be overlooked for promotions and employment opportunities because of their age and likelihood of retiring. Pensions are no longer the economic mainstay of retirement. The recent pandemic from coronavirus disease 2019 (COVID-19) accelerated unemployment and retirements of older workers who often had health issues, increasing their risks of contracting the deadly disease. Food insecurity became commonplace (Wolfson & Leung, 2020).

Leisure and Social Activities

As with younger populations, lifestyle is crucial in late adulthood. As age increases, participation in leisure and social activities decreases for many people. Health conditions such as depression, lung disease, and diabetes may prevent participation in home maintenance and leisure activities, especially walking, gardening, and active sports. Maintaining a positive mental attitude and participating in cognitively engaging, regularly scheduled leisure activities appear to exert a protective factor and is associated with a reduced risk of dementia even after adjusting for baseline cognitive status. Higher education levels are also associated with increased participation in both formal and informal activities (Gholamnezhad et al., 2020).

Family Relationship Changes

As family relationships change, interpersonal relationship strains can develop. Disappointments with the lifestyles of adult children and changes in caregiving responsibilities affect the quality of a long-term family relationship. In some instances, the young-old assume caregiving responsibilities for their old-old relatives. It is also common for grandparents to assume some caregiving responsibilities for their grandchildren. Although there are stresses associated with grandparenting, positive benefits appear to outweigh negatives except when combined with other intensive caregiving (Arpino & Gómez-León, 2020). The frequency of grandparents raising grandchildren in co-parenting and custodial households has increased significantly in the past 35 years, occurring most frequently in African American families (Whitley et al., 2016).

Cultural Impact

With our communities increasingly becoming a reflection of multiple ethnic histories and values, the aging population is likewise becoming more diverse. In 2010, 80% of the adults aged 65 years or older were non-Hispanic White. By 2030, older non-Hispanic White adults will make up 71.2% of the population, whereas Hispanics will make up 12%, non-Hispanic Blacks nearly 10.3%, and Asian American 5.4%. By 2050, older non-Hispanic White adults will account for only about 58% of the total population aged 65 or older (CDC, 2020a). Underrepresented groups face disparities in access to and provision of health care. At the same time, they have higher-than-average health care needs (Borson et al., 2019). Cultural variations also exist in family expectations of and responsibilities for older adults. For example, some groups, such as the Chinese, tend to highly value the experience and wisdom of their elders, and family members feel a responsibility for their care (Ma & Saw, 2020).

Community Factors

Although most older adults live in their own homes, they may find themselves living in changing or deteriorating neighborhoods with inadequate social resources, such as place of worship and community, shopping, and health care centers. Relocating to smaller and more protective housing may be welcomed by

some and fiercely resisted by others.

Residential Care

Residential care in foster care homes, family homes, personal care homes, residential care facilities, or assisted living arrangements provides the older adult with a protected environment. The quality of services and affordability of the arrangement need to be carefully evaluated to determine whether the older adult's needs and abilities match the care provided in that facility, including staff training and staffing patterns, medication supervision, approaches to behavior management, activities provided, services available (e.g., care management, family support, counseling, day care), safety and security issues, provision of personal care with attention to dignity and privacy, health and nutrition concerns, full disclosure of costs and funding, and payment issues.

RISK FACTORS FOR OLDER ADULT PSYCHOPATHOLOGY

Chronic Illnesses

Although the frequency of acute conditions declines with advancing age, about 80% of older adults have at least one chronic health condition; 50% have at least two. Poor physical health is associated with mental disorders both as a risk factor and as an outcome, with those with severe disabilities reporting lower levels of well-being (Happell et al., 2017). Common chronic conditions that cause activity limitation include arthritis, hypertension, heart disease, and respiratory disorders. Chronic illnesses can reduce physiologic capacity and consequently increase functional dependency. In addition, during acute episodes of illness, many older adults lose functional ability because they have limited reserves or cannot mobilize reserves to regain their premorbid performance levels.

Alcohol Use Disorder and Substance Use Disorder

Alcohol use disorder and substance use disorder are underestimated and undertreated. Substance use disorder is associated with poor health outcomes, higher health care utilization, and increased complexity of the course of the disorder. In addition, older adults with substance use disorder problems have increased disability and impairment, compromised quality of life, increased caregiver stress, increased mortality, and a higher risk of suicide. Excessive alcohol use accounts for more than 21,000 deaths each year among adults 65 years or older (Chhatre et al., 2017). The majority of older adults with substance use disorder do not receive adequate treatment (Rhee & Rosenheck, 2020).

Polypharmacy

More than 87% of older adults use prescription medication. The prevalence of **polypharmacy**, the use of five or more medications, in older adults ages 62 to 85 years is 90% in long-term care facilities (Talebreza & McPherson, 2020). The aging process affects pharmacokinetics and the strength and number of protein-binding sites (see [Chapter 11](#)). These changes place older adults at increased risk for adverse drug reactions. Difficulties in managing medications arising from memory impairment further compound the problem of medication misuse. Serious problems result when the treatment regimen and care delivery specific to prescribed medications are not coordinated. These problems are compounded when an older adult uses over-the-counter drugs, herbal remedies, and home or folk remedies without considering their potential interaction with prescribed drugs. Prescribers can follow the principles delineated in [Box 18.3](#) to improve drug therapy in the older adult population.

BOX 18.3

Drug Therapy Interventions

- Minimize the number of drugs that the patient uses, keeping only those drugs that are essential. One third of the residents in one long-term care facility received 8 to 16 drugs daily.
- Always consider alternatives among different drug classifications or dosage forms that are more suitable for older adult patients.
- Implement preventive measures to reduce the need for certain medications. Such prevention includes health promotion through proper nutrition, exercise, and stress reduction.
- Most age-dependent pharmacokinetic changes lead to potential accumulation of the drug; therefore, medication dosages should start low and go slow.

- Exercise caution when administering medication with a long half-life or in an older adult with impaired renal or liver function. Under these conditions, the time may be extended between doses.
- Be knowledgeable of each drug's properties, including such factors as half-life, excretion, and adverse effects (e.g., venlafaxine HCl [Effexor], a structurally novel antidepressant that inhibits the reuptake of serotonin and norepinephrine, requires regular monitoring of the patient's blood pressure).
- Assess the patient's clinical history for physical problems that may affect excretion of medications.
- Monitor laboratory values (e.g., creatinine clearance) and urinary output in patients receiving medications eliminated by the kidneys.
- Monitor plasma albumin levels in patients receiving drugs that have high binding affinity to protein.
- Regularly monitor the patient's reaction to all medications to ensure a therapeutic response.
- Look for potential drug interactions that may complicate therapy. Antacids lower gastric acidity and may decrease the rate at which other medications are dissolved and absorbed.
- Instruct patients to consult with their providers before taking any over-the-counter medications.

Bereavement and Loss

Older adults experience many losses—friends and family members die, physical health can be compromised, choices and independence may be limited, and social status may diminish. Loss of one's spouse, particularly when the relationship has been long and satisfying, constitutes a major life event. Women are more likely to lose their spouses and tend to be widowed at a younger age than are men. Consequently, women have more time to adjust and develop substitute social relationships to replace the spouse. Conversely, men tend to lose their wives at an older age, have fewer social networks to replace the spouse, and express feelings of loneliness and abandonment. Because of differences in longevity, men and women usually experience life events at different ages. Regardless of gender differences, survivors are at higher risk for depression and face financial issues after the death of a loved one. Health care professionals should work closely with grieving survivors to help them understand that their lives will be displaced for some time. Support sessions on the grief process and financial and employment planning could become a standard part of care.

Older Adults Experiencing Poverty

In the past 50 years, the number of individuals experiencing poverty aged 65 and older has steadily decreased, from 28.5% in 1966 to 9.2% in 2017. In 2018, three million older Whites (7.3%) were poor, compared to 18.9% of older African Americans, 11.7% of Asians, and 19.5% of older Hispanics (Administration for

Community Living, 2020). Whereas the proportion of older adults who live in poverty has decreased, the number of aged poor has increased from 3.1 million in 1974 to 44.7 million in 2017. However, certain groups are more vulnerable to poverty than others, including widows, divorced women, and never married men and women. Individuals aged 80 and older have the highest poverty rate, especially women. The poverty rate of women aged 80 and older is 13.5% compared with 8.7% for men. Poverty rates also vary by race in older adults. The poverty rate is lowest among the non-Hispanic White population (5.8% for men and 8.0% for women) and highest among the Black population (16.1% for men and 21.5% for women) (Li & Dalaker, 2019).

The aging of the population has significant implications for healthcare costs associated with Medicare as two million baby boomers were eligible to sign up by the end of 2015.

Social Isolation

Social isolation, the relative absence of social relationships, is recognized as detrimental to quality of life and premature mortality. Meaningful interactions are important to the physical and mental health of older adults. Staying active, continuing to work, caring for others, and/or engaging with family, friends, and community contribute to the well-being of the older person. Since the older adult population was very vulnerable to COVID-19 transmission, social isolation became a strategy to prevent transmission of the illness. While social isolation protected many from physical illness, it led to negative consequences of loneliness and depression (Smith et al., 2020). As a result of the sheltering in place and other social distancing strategies, loneliness is higher than prior to the pandemic and associated with depression and suicidal ideation (Killgore et al., 2020).

Lack of Social Support and Suicide

Closely related to social isolation, a lack of social support is linked to transition into an institutional setting. When older adults can go to movies, dinner, or a casino and visit family and friends, they are more likely to remain in independent living. Dissatisfaction with social life, lack of participation in

organizations, and being distant from others are associated with a wish for death (Bernier et al., 2020; Oh, 2019). Safety concerns are always a priority. Any suicidal ideation should be identified and a safety plan developed (see [Box 18.4](#)).

BOX 18.4

Risk Factors for Suicide in Late Life (Age Older than 65 Years)

- Depression
- Prior attempts at suicide
- Marked feelings of hopelessness; lack of interest in future plans
- Feelings of loss of independence or sense of purpose
- Medical conditions that significantly limit functioning or life expectancy
- Impulsivity due to cognitive impairment
- Social isolation
- Family discord or losses (i.e., recent death of a loved one)
- Inflexible personality or marked difficulty adapting to change
- Access to lethal means (i.e., firearms, other weapons, etc.)
- Daring or risk-taking behavior
- Sudden personality changes
- Alcohol or medication misuse or abuse
- Verbal suicide threats such as, “You’d be better off without me” or “Maybe I won’t be around”
- Giving away prized possessions

Mental Health America. (2021). Preventing suicide in older adults.

Shared Living Arrangements and Older Adult Mistreatment

Older adult mistreatment, intentional actions that cause harm or create a serious risk of harm to a vulnerable older adult by a caregiver or other person who stands in a trust relationship to the individual, has an estimated prevalence of 10%. Actual cases may actually be 14 times the number of reported cases (National Center on Elder Abuse [NCEA], 2017). Clinical and empirical evidence suggests that a shared living arrangement increases the opportunities for contact that can lead to conflict and mistreatment. Abuse of older adults tends to take place where the individuals live: most often in the home where abusers are apt to be adult children, other family members such as grandchildren, or spouses or partners of older adults. Institutional settings, especially long-term

care facilities, can also be sources of abuse. The prevalence of mistreatment of the older adult appears to be related to low income, poor health, and lack of social support. Race and ethnic differences have not been shown to play a role (Hernandez-Tejada et al., 2020).

PROTECTIVE FACTORS FOR MENTAL ILLNESS IN OLDER PERSONS

Protective factors for minimizing the occurrence of mental disorders in older adults are similar to those in younger adults. Evidence supports protective factors, which include marriage, education and income level, resilience—and positive outlook, healthy lifestyle, nutrition, and exercise.

The Marriage Effect

It has long been thought that married people have lower mortality rates than unmarried at all ages. Many studies have reported that being part of a couple and the quality of the relationship are positively correlated with longevity and health, including cognitive and emotional function (Karimi et al., 2019). There are several possible explanations for the marriage advantage. For example, married people may be less likely to engage in high-risk and health-damaging behaviors. They may also be more likely to receive care and support when needed. They have shared economic resources and a social network of relatives and friends who can provide vital support at older ages. Negotiating a partner relationship that presents ongoing social and emotional challenges may also contribute to higher functioning (see [Fig. 18.1](#)).

Education and Income

Education and income provide older adults with cognitive, economic, and coping reserves that support function and well-being and are related to physical activity and physical and cognitive function and disability. Those with higher education and income are more likely to engage in physical activity and have the resources

to provide care when needed. Higher levels of education are associated with higher levels of cognitive function as well as a lower risk of dementia (Arce Rentería et al., 2019).

FIGURE 18-1: Lifelong marriage is associated with positive physical and mental health. (Rawpixel/Shutterstock.)

Resilience and Positive Outlook

Research has shown that those with a positive attitude toward aging age better and live longer. Although it is not known why a positive attitude increases longevity, it is thought to be linked to the will to live, **resilience** (i.e., the ability to adapt successfully to stress, trauma, or chronic adversity), and a proactive approach to health. It may also be that people with a positive attitude have lower stress. Research has proposed that resilience enables one to adapt positively to adversity, and characteristics associated with resilience include optimism, social engagement, emotional well-being, fewer cognitive complaints, and successful aging (Calderón-Larrañaga et al., 2019).

Healthy Lifestyle

A healthy lifestyle is important in preventing illness and promoting well-being at all ages, including in late adulthood. Such behaviors include not smoking; drinking alcohol in moderation; getting adequate rest and sleep; getting adequate hydration and nutrition, especially fruits and vegetables; exercising; and coping with stress (Perera & Agboola, 2019).

Nutrition

Maintaining a healthy diet can be challenging for older adults. In the United States, the prevalence of obesity is 42.5% of all adults over the age of 60 (CDC, 2020b). The prevalence of undernutrition appears to be high in older adults, especially those living in an institutionalized setting (17%) (Kiesswetter et al., 2020). Factors contributing to undernutrition include living alone, poor appetite, poor intake of fluid and nutritious foods, medications, malignancy, bereavement, and depression. Undernutrition can lead to anemia, inadequate wound healing, increased incidence of pressure sores, impaired elimination, impaired immunologic functions, weakness, fatigue, and mental problems (including depression, dementia, and agitation) (Saxon et al., 2015). Adequate nutrition is an important factor in maintaining mental health.

Physical Activity

Emerging evidence suggests that physical activity is related to positive mental health and may be a protective factor. There is a moderate amount of evidence that exercise can prevent the onset or worsening of depression. Structured exercise programs enhance older persons' overall physical functioning and well-being and reduce anxiety symptoms among sedentary adults with chronic illnesses (Miller et al., 2020).

INTERVENTION APPROACHES

Reducing the Stigma of Mental Health Treatment

The stigma of mental illness continues to interfere with the willingness of older

adults to seek treatment. Older adults in America grew up during a time when institutionalization in asylums, electroconvulsive treatments, and other treatment approaches were regarded with fear. This fear can lead to denial of problems. Nurses can help reduce the stigma through educational interventions and facilitation of access to services.

Early Recognition of Depressive Symptoms and Suicide Risk

Depression is one of the most common mental disorders in older adults (see [Chapter 23](#)). Even with a high usage of psychotropic medications, depression remains untreated in this population (Blazer & Steffens, 2019). Because depression can be debilitating and can lead to suicide, recognition and early intervention are the keys to avoiding ongoing depressive episodes. Depressive symptoms among older adults are more likely to include vague somatic complaints, cognitive symptoms, hypersomnia, and appetite changes rather than complaints of depressed mood. Early indications of symptomatology can be identified in primary care settings using a screening tool such as the Geriatric Depression Scale (Yesavage et al., 1982). Several preventive interventions are helpful, such as grief counseling for widows and widowers, self-help groups, and physical and social activities.

Monitoring Medications

With the approval of new medications, older adults' health problems can be treated with pharmacologic agents that were not previously available. It is important to make sure that medications are being taken correctly as well as whether they are having the desired effects. Side effects and drug interactions should be carefully monitored to detect untoward symptoms and delirium. Dosages may need to be adjusted slowly. It is important to review all medications, including over-the-counter, natural, and alternative remedies.

Avoiding Premature Institutionalization

Although many people require nursing home care, integrated care in the community is effective and can delay nursing home placement. Home visits that focus on assessment of symptoms and coordination of health care needs can result in older adults receiving their mental health support within the community and, therefore, are able to stay in their current living arrangements. Older adults and those with disabilities prefer to receive community-based care, which to be most effective must include prevention and rehabilitation services as well as acute care.

Promoting Mental Health

Social Support Transitions

Compensating for loss of family by expanding friendship networks and employment may become an important method of establishing a network in late life. Older adults can be prepared for the transition by receiving information about internal developmental processes, sources of social support, and opportunities for personal growth and role supplementation. Interventions to support successful aging promote productive and social engagement, and effective coping groups can be particularly effective in developing a sense of community, decreasing isolation, and strengthening a safety network.

Cognitive Engagement

Frequent engagement in cognitive activities may positively impact cognitive functioning in memory. Successful cognitive aging appears to be supported not only by cognitive reserve but also by the older adult's development and use of compensatory strategies. For example, a nursing intervention would be teaching the patient to write notes to self about upcoming events. Such compensatory strategies support cognitive functioning as well as a sense of personal control.

Lifestyle Support

Lifestyle interventions, such as exercise promotion and nutrition counseling, are particularly important in late life because a tendency to slow down and become more sedentary usually accompanies aging. For many, retirement provides an opportunity to restructure the time that was previously spent working. Developing regular exercise habits can help maintain physical and psychological well-being, especially if done with others. Self-help programs generally include components of exercise, nutrition, health screening, and health habits. Maintaining social support is an integral part of lifestyle support.

Self-Care Enhancement

Enhancing health self-care is a major area for mental health promotion. Education of older adults and their families is crucial to ensuring adherence to agreed-upon care regimens. The nurse must consider the individual's educational level, pace of learning, and visual and hearing deficits. The nurse should provide instructional aids, large-print labeling, and devices such as medication calendars that encourage adherence. Self-care enhancements assist older adults in the use of compensatory strategies and aid in their being as functionally independent as possible for as long as possible. Supporting a sense of control and decisional capacity is critical to self-care.

Spiritual Support

Spirituality can be extremely important to older adults and can positively affect attitude, particularly as health declines. Participation in a community of faith is associated with better health outcomes and mental well-being (Lima et al., 2020). Supporting contact with spiritual leaders important to the patient is an ongoing mental health promotion intervention. The nurse can also support a patient's spiritual growth by exploring the meanings that a particular life change has for the patient. In late life, existential issues such as experiencing losses, redefining meanings in existence, and living in the present become the standard, replacing the performance and future orientation that characterize earlier adulthood.

Community Services

Community care options are needed that provide both sustenance and growth. Examples of supportive services that foster independent community living include information and referral services; transportation and nutrition services; legal and protective services; comprehensive older adult community centers; homemaker and handyman services; matching of older with younger individuals to share housing; and use of the supports available through places of worship, community groups, or mental health and other community agencies (e.g., area agencies on aging) to maintain older adults in the community for as long as possible. The availability and accessibility of these services vary greatly, and eligibility requirements may exist.

POSITIVE MENTAL AGING

At this time, there are many questions about the course of aging for future cohorts of older adults. It is probable that some of the losses and decrements associated with aging are in fact artifacts of a more sedentary, less healthy lifestyle over a lifetime. Furthermore, we must consider that positive mental aging is more than the absence of mental disorders and impairment but rather is more a reflection of resilience—the capacity to adapt, feel in control, and make decisions about care and life. Most important is to listen to older adults themselves. Research shows that four qualities contribute to successful aging: the capacity to adapt to change, engagement and involvement in life, the importance of stability and security with reliable social support, and, least important, physical health (Jeste et al., 2013). As nurses, it is incumbent upon us to help older adults to recognize and use their strengths to cope with and transcend losses and limitations. Recognizing and tapping into the wisdom accumulated over a lifetime may help older adults to negotiate the many challenges faced in later life.

SUMMARY OF KEY POINTS

- Changes in vital biologic structures and processes occur, but older adults can

sustain some structural losses without losing function.

- All five senses (sight, hearing, touch, taste, and smell) decline with age, which may affect information processing.
- Although older adults experience many physical changes, they can and have the desire to remain sexually active.
- Threats to cognitive function in older adults include medication side effects, depression, poor nutrition, infection, heart and lung disease, thyroid problems, alcohol use, and sensory loss.
- Intelligence and personality are stable throughout the life span; however, reaction time slows with age.
- Major changes in social roles with aging include retirement, loss of partner, and changes in residence.
- Polypharmacy is prevalent in older adults, particularly in nursing homes. Ongoing assessment of medications is needed to prevent inappropriate medication administration.
- Older people are at higher risk for poverty and suicide.
- Older adults are vulnerable to COVID-19, which leads to social isolation and increased mortality.
- Mental health protective factors include marriage, education, resilience and positive outlook, and healthy lifestyle (including nutrition and exercise).
- Interventions to prevent mental illness include reducing the stigma of mental health treatment, preventing depression and suicide, monitoring medications, and preventing premature institutionalization.
- Nurses can provide a number of interventions to promote mental health, addressing social support transitions, cognitive engagement, lifestyle support, self-care enhancement, spiritual support, and community-based services.
- Positive mental aging is more than the absence of mental disorders and impairment but rather is more a reflection of resilience, which is the capacity to adapt, feel in control, and be engaged, with a positive outlook.

CRITICAL THINKING CHALLENGES

1. Compare the three late adulthood chronologic groups in terms of age. Using the recommendations in [Box 18.1](#), interview people representing each of the three chronologic groups about their views of mental health.
2. Highlight normal biologic changes that occur during the aging process.
3. Hypothesize why IQ tests and personality do not change with time.
4. Explain the concept of gerotranscendence and use the concept to explain differences between the young-old and the old-old.
5. Identify positive and negative perspectives of retirement.
6. Explain why chronic illnesses, polypharmacy, and poverty are all risk factors for mental health problems in later life.
7. Describe mental health promotion interventions that relate to social support transitions, cognitive engagement, lifestyle support, and self-care.
8. Describe factors that contribute to successful aging.

Movie Viewing Guides

Driving Miss Daisy: 1989. This delightful film stars Jessica Tandy as Daisy Werthan, a cantankerous older woman. Morgan Freeman plays Hoke Colburn, Daisy's chauffeur. This beautiful story examines a relationship between two people who have more in common than just getting old. *Driving Miss Daisy* challenges some of the myths about getting old.

VIEWING POINTS: Identify the normal behaviors in the growth and development of older adults. Observe the verbal and nonverbal communication of Daisy and Hoke. How do they support each other?

Stress and Mental Health

Kelley McGuire

KEYCONCEPTS

- appraisal
- allostatic load
- adaptation
- coping
- stress

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Discuss the concept of stress as it relates to mental health and mental illness.
2. Differentiate acute stress from chronic stress.
3. Discuss the factors that lead to allostatic load.
4. Discuss psychosocial factors that influence the experience of stress.
5. Discuss the variety of stress responses experienced by individuals.
6. Explain the role of coping and adaptation in maintaining and promoting mental health.
7. Apply critical thinking skills to the nursing process for a person experiencing stress.

KEY TERMS

- Acute stress
- Allostasis
- Chronic stress
- Diathesis
- Emotion-focused coping
- Emotions
- General adaptation syndrome
- Homeostasis
- Problem-focused coping
- Reappraisal
- Social functioning
- Social network
- Social support
- Stress response
- Transactional stress model

INTRODUCTION

Stress is a natural part of life, yet it is one of the most complex concepts in health and nursing. Although often thought of as negative, depending on the source of the stress, it can be a positive experience. During severe stress, some people draw on resources that they never realized they had and grow from those experiences. However, early childhood stress and trauma, unresolved stress, or chronic stress can have negative mental and physical health consequences.

Stress is also associated with the development or exacerbation of symptoms of mental illness. For example, a stressful event may precipitate a psychosis. Family caregivers can develop depression as they continually monitor their family member, cope with illness-related behaviors, and often witness deterioration of their partner (Crespo et al., 2019).

Stress is approached from several overlapping theoretical perspectives—physiologic, psychological, and social. Consequently, there are many definitions of stress depending upon the theoretical perspective. This chapter provides an overview of the major evidence-based theories of stress and describes the applicability of the models in the practice of nursing.

BIOLOGIC PERSPECTIVES OF STRESS

Physiologic responses to stress are automatic and differ based on the event, duration, and intensity. Homeostasis and allostasis are the foundation of the physiologic responses to stressful events.

Homeostasis versus Allostasis

The concept of **homeostasis**, which is the body's tendency to resist physiologic change and hold bodily functions relatively consistent, well-coordinated, and usually stable, was introduced by Walter Cannon in the 1930s. The body's internal equilibrium is regulated by physiologic processes such as blood glucose, pH, and oxygen; set points (normal reference ranges of physiologic parameters) are maintained (Cannon, 1932).

Allostasis is a term used to describe how the body adapts to maintain

physiologic stability. Allostasis is a dynamic regulatory process involving functions of the autonomic nervous system, the hypothalamic–pituitary–adrenal (HPA) axis, and the cardiovascular, metabolic, and immune systems respond to internal and external stimuli (McEwen, 2017).

Acute Stress

Acute stress, an intense biopsychosocial reaction to a threatening event, is time limited (usually less than a month) but can occur repeatedly. It can lead to physiologic allostatic load/overload, which in turn can have a negative impact on a person’s health (McEwen, 2017).

Acute stress is associated with the “fight-or-flight” response. When the brain (amygdala and hippocampus) interprets an event as a threat, the hypothalamus and autonomic nervous system are signaled to secrete adrenaline, cortisol, and epinephrine. These hormones activate the sympathetic nervous system and physiologic stability is challenged. A “fight-or-flight” response occurs when the heart rate, blood pressure, and blood sugar increase. Energy is mobilized for survival. As the sympathetic system is activated, the parasympathetic is muted (Table 19.1). After there is no longer a need for more energy and the threat is over, the body returns to a state of homeostasis.

Chronic Stress

Chronic stress is an ongoing physiologic reaction to events resulting in “wear and tear” on the body and negatively impacts health and well-being. The adaptive physiologic changes that occur during acute stress become maladaptive when prolonged and contribute to the risk for illness. The relationship between chronic stress and illness was identified many years ago with the introduction of the general adaptation syndrome (GAS).

TABLE 19-1: FIGHT AND FLIGHT: PHYSIOLOGIC CHANGES

Parasympathetic

Sympathetic Nervous System Effect	Purpose	Nervous System Conservation of Energy
Increased serum glucose	Increased energy	Decreased sexual and sex hormone activity
Increased cardiac output and blood pressure (increase in renin and angiotensin)	Increased blood flow	Decreased growth, repair, and maturation
Increased oxygen tension and hematocrit	Increased supply of oxygen in blood	Decreased digestion, assimilation, and whole food distribution
Other Physiologic Changes		

Effect	Purpose
Increased immune responses	Reduced risk of infections
Heightened vigilance in the brain	Increased decision-making attention and memory
Hyperactivation of the hemostatic and coagulation system	Prevention of excessive bleeding from wounds

Adapted from Diamond, J. W. (2009). Allostatic medicine: Bringing stress, coping, and chronic disease into focus: Part 1. *Integrative Medicine*, 8(6), 40–44.

General Adaptation Syndrome

Hans Selye, who is credited with initiation of the study of stress, defined stress as a nonspecific response to an irritant, a perceived danger, or a life threat. He called stress evoked by positive emotions or events *eustress* and stress evoked by negative feelings and events *distress*. He showed that corticosteroid secretion from the pituitary gland increased during stress and contributed to development of illnesses. Selye described this process as **general adaptation syndrome (GAS)** (Selye, 1956, 1974). This early work set the stage for our understanding of the role of the HPA in chronic stress.

When the HPA axis is activated under conditions of stress, the hypothalamus

secretes corticotropin-releasing hormone, because of which the pituitary gland increases secretion of adrenocorticotrophic hormone (corticotropin), which in turn stimulates the adrenocortical secretion of cortisol. Over time, excessive exposure to cortisol contributes to the dysregulation of the autonomic nervous system.

Allostatic Load

Allostatic load (AL) is a term used to describe the wear and tear on a person's body and brain resulting from chronic stress. The cumulative changes of the biologic regulatory systems (cardiovascular, metabolic, and immune) is indicated by abnormal laboratory values and may increase the risk of disease and illness. As wear and tear on the brain and body occurs, there is a corresponding increase in the AL (Fig. 19.1). The greater the AL, the greater the state of chronic stress and, ultimately, the more negative changes in health (Guidi et al., 2021; McEwen, 2017).

KEYCONCEPT **Allostatic load** is the consequence of the wear and tear on the body and brain and leads to ill health.

Paradoxically, the same systems that are protective in acute stress can damage the body when activated by chronic stress. The benefits of the increase in circulating cortisol to the human body are initially adaptive, but if it continues, it can be quite damaging to both mental (depression) and physical (immune, cardiovascular, and metabolic) health (Anisman, 2015; McVicar et al., 2013; Sterling, 2012).

Consequences of Chronic Stress

In chronic stress, the immune system is suppressed. Cortisol is primarily immunosuppressive and contributes to reduction in lymphocyte numbers and function (primarily T-lymphocyte and monocyte subsets) and natural killer activities. The immune cells have receptors for cortisol and catecholamines that can bind with lymphatic cells and suppress the immune system. The continuous sustained activation of the sympathetic nervous system; HPA axis; cardiovascular, metabolic, and immune systems contribute to a hormonal

overload, leading to impairment in memory, immunity, cardiovascular, and metabolic function (McEwen, 2017).

Over time, chronic stress compromises health and increases susceptibility to illnesses. For instance, children who have suffered psychological neglect, abuse, or parental loss are more likely to experience elevated AL in adulthood (Guidi et al., 2021). Elevation of white blood cell counts and lower counts of T, B, and natural killer cells are found in those who face academic examinations, job strain, caregiving for a family member experiencing dementia, marital conflict, and daily stress. Altered parameters of immune function are present in those with negative moods (chronic hostility, depression, and anxiety), social isolation, and marital disagreement. Antibody titers to Epstein–Barr and herpes simplex viruses are also elevated in stressed populations. If the stress is long term, the immune alteration continues (McEwen, 2017).

FIGURE 19-1: The development of allostatic load in response to stress. (Redrawn from McEwen, B. S. [1998]. Protective and damaging effects of stress and stress mediators. *New England Journal of Medicine*, 3[38], 171–179. Copyright © 1998 Massachusetts Medical Society. BOX 19.1

Research for Best Practice: Allostatic Load

Chyu, L. & Upchurch, D. M. (2018). A longitudinal analysis of allostatic load among a multi-ethnic sample of midlife women: Findings from the study of women's health across the nation. Women's Health Issues, 28(3), 258–266.

THE QUESTION: Does AL increase over time (reflecting health declines and physiological aging) in midlife women (42–52 years old)? Is lower socioeconomic status associated with higher AL?

METHODS: A community-based, multisite, prospective study examined biopsychosocial changes during menopausal transition among a cohort of midlife women (N = 1,932; 13,391 observations). Ten biomarkers were used to represent AL across cardiovascular, inflammatory, metabolic, and neuroendocrine systems. AL scores were calculated at baseline and at annual visits at seven time points. Higher AL scores indicated poorer health.

FINDINGS: Older age at baseline, lower household income, African-American race, and speaking and reading English only were significant predictors of higher AL scores.

IMPLICATIONS FOR NURSING: AL can be used to identify high-risk women and begin early prevention and intervention to reduce disease burden and disparities at the population level.

Health disparities found in lower socioeconomic groups, racial and ethnic minorities, and older adults may be partly explained by the chronic stress they tend to experience. These groups have been found to have elevated AL. AL has been found to differ by race, where Black Americans display greater levels than White Americans. Further, the effects of elevated AL may present differently based on gender, where high AL is more often associated with depression in Black men and White women than their corresponding counterpart (Guidi et al., 2021; McEwen, 2017) (see [Box 19.1](#)).

Chronic Stress and Mental Illness

When stress is associated with the development or exacerbation of a mental illness, the diathesis–stress model can be applied. A **diathesis** is a genetic predisposition that increases susceptibility of developing a disorder. This model describes how stress can trigger the development or exacerbation of an illness (Kalamatianos & Canellopoulos, 2019). Exposure to childhood trauma can lead to negative long-term health consequences on mental and physical health throughout life (American Society for the Positive Care of Children, 2021); for example, a woman whose mother had a long history of depression (indicating a genetic predisposition to mental disorders for the daughter) and who was assaulted as she was leaving work and sustained multiple injuries. Her first manic episode occurred within 2 months (see [Chapter 22](#)).

No one lives in a stress-free environment, yet stress reduction leads to positive mental health. Conversely, many patients attribute their first illness episode to a stressful event such as an assault, rape, or family tragedy.

PSYCHOSOCIAL PERSPECTIVES OF STRESS

The **Transactional Stress Model** describes the psychological experience of stress. This model views stress as an interactive process arising from real or perceived internal or external environmental demands that are appraised as threatening or benign (Fig. 19.2) (Lazarus & Folkman, 1984). The external environment includes physical aspects such as air quality, cleanliness of food and water, temperature, and noise and social aspects such as living arrangements and personal contacts.

KEYCONCEPT Stress is a process arising from real or perceived internal or external environmental demands that are appraised as threatening or benign (Lazarus & Folkman, 1984).

Appraisal

Appraisal is the individual perception that an event or situation is a threat. One situation may be perceived as threatening to one person but not to another (Box 19.2). The more important or meaningful the event, the more vulnerable the person is to stress. For example, chest pain is threatening not only because of the immediate pain and incapacitation but also because the pain may mean a heart attack is occurring. The individual is afraid that they may not have the physiologic resources to survive the attack.

KEYCONCEPT is the process where potentially stressful events are evaluated for meaning and significance to individual well-being (Lazarus & Folkman, 1984).

Appraisal is a complex process that includes many aspects—the demands, constraints, and resources are balanced with personal goals and beliefs. A critical factor is the risk that the event poses to a person's well-being (Carpenter, 2016; Lazarus, 2001).

The appraisal process has two levels: primary and secondary. In a primary appraisal, a person evaluates the events occurring in their life as a threat, harm, or challenge. During primary appraisal of an event, the person determines whether (1) the event is relevant, (2) the event is consistent with their values and beliefs, and (3) a personal commitment is present. In the vignette, Susan's commitment to the goal of doing well on the test was consistent with her valuing

the content, which in turn motivated her to study regularly and prepare carefully for the examination. She believed that the test would be difficult. Joanne had a commitment to pass the test but did not value the content. Unlike Susan, Joanne believed that the test would be relatively easy because she expected the questions to be the same as those on the previous examination.

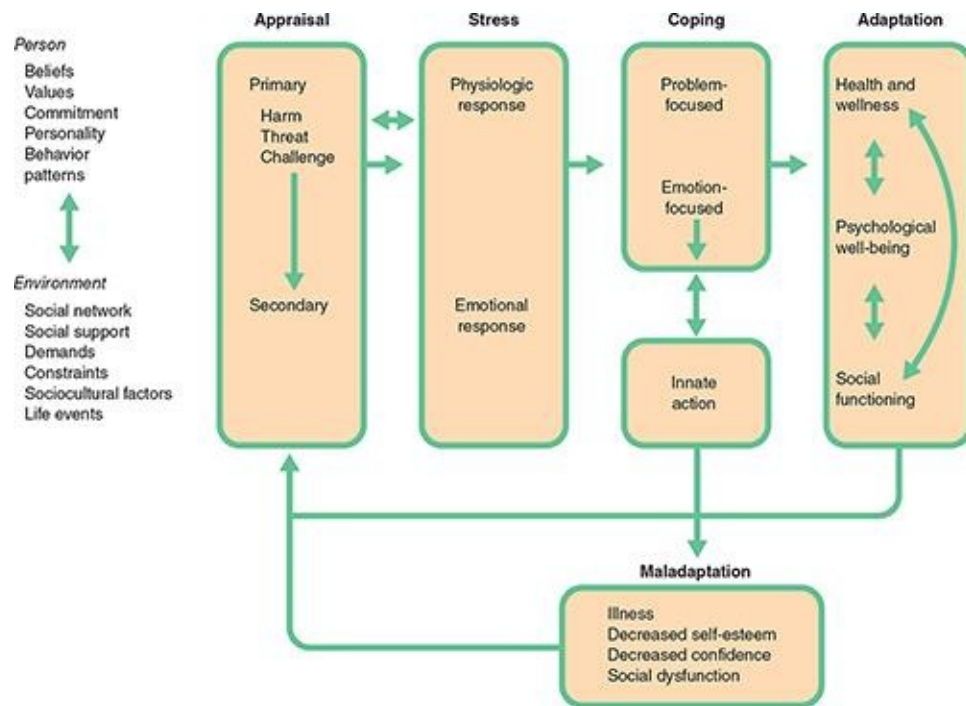

FIGURE 19-2: Stress, coping, and adaptation model.

BOX 19.2 CLINICAL VIGNETTE

Stress Responses to an Examination

Two students are preparing for the same examination. Susan is genuinely interested in the subject, prepares by studying throughout the semester, and reviews the content 2 days before test day. The night before the examination, she goes to bed early, gets a good night's sleep, and wakes refreshed but is slightly nervous about the test. She wants to do well and expects a difficult test but knows that she can retake it at a later date if she does poorly.

In contrast, Joanne is not interested in the subject matter and does not study throughout the semester. She “crams” 2 days before the test date and does an “all-nighters” the night before. This is the last time that Joanne can take the examination, but she believes that she will pass because she has already taken it twice and is familiar with the questions. If she does not pass, she will not be able to return to school. On entering the room, Joanne is physically tired and somewhat fearful of not passing the test. As she looks at the test, she instantly realizes that it is not the examination she expected. The questions are new. She begins hyperventilating and trembling. After yelling obscenities at the teacher, she storms out of the

room. She is very distressed and describes herself as “being in a panic.”

What Do You Think?

- How are the students’ experiences different? Are there any similarities?
- Are there any nursing diagnoses that apply to Joanne’s situation?

In a secondary appraisal, the person determines if they possess the necessary coping mechanisms to overcome the event. In the example, Susan was nervous but took the test. Joanne’s secondary appraisal of the test-taking situation began with the realization that she might not pass the test because the questions were different. She acted impulsively by blaming the teacher for giving a different examination and storming out of the room. She clearly did not cope effectively with a difficult situation.

Values and Goals

Cultural, ethnic, family, and religious values shape the significance and importance of the event. For example, one person may value a high-paying salary and another may value the freedom to move around without the boundaries of material things.

If a goal (such as maintaining an important position) is important, a person is more likely to do what it takes to reach the goal. The more important the goal or the more difficult the goal is to obtain, the greater the likelihood of stress. For example, students who earn mostly or all As often feel more stress about examinations than do students who earn Bs and Cs because the higher grade is more difficult to obtain.

Personality Types

Personality influences the appraisal process and the ability to cope with the stress. The association of personality types to health or illness status has been studied for more than 50 years (Friedman & Rosenman, 1974). There are four general personality types. Type A personalities are characterized as competitive, aggressive, ambitious, impatient, alert, tense, and restless. They think, speak, and act at an accelerated pace and reflect an aggressive, hostile, and time-urgent style of living that is often associated with increased psychophysiologic arousal

(Bokenberger et al., 2014; Roy, 2018). In contrast, type B personalities do not exhibit these behaviors and generally are more relaxed, easygoing, and easily satisfied. Type B personalities are less likely than Type A personalities to engage in risky health behaviors such as alcohol consumption and smoking. Type B personalities are also more likely to practice preventative care measures and wellness activities (Korotkov et al., 2011). Type B personalities are described as accepting and relaxed. They are unlikely to experience a lack of time for commitments and are able to commit time for relaxation (Iswari, 2020).

Type C personalities are described as having difficulty expressing emotion and are introverted, respectful, conforming, compliant, and eager to please and avoid conflict. They respond to stress with depression and hopelessness. This personality type was initially associated with the development of cancer, specifically breast cancer in women, presumably due to the changes that occur within endocrine and immune function (Lalaš et al., 2010; Romo-González et al., 2018). It is more likely that this personality type will experience more depression and difficult marital adjustment (Bozo et al., 2017).

Type D (distressed) personalities experience a tendency toward negative emotions and pessimism. These individuals are more likely to be socially inhibited and are unlikely to show their emotions to others. Despite some overlap, the characteristics of type D personalities are different than depression and anxiety (Kim et al., 2020). There is mixed research support for an association between a type D personality and mental health disorders and poor physical health status (Marchesi et al., 2014; Stevenson & Williams, 2014). Emerging data suggest that type D personality is related to outcome severity of acute coronary syndrome and diabetes (Conti et al., 2016; Garcia-Retamero et al., 2016).

Social Networks

A **social network** consists of linkages among a defined set of people with whom an individual has personal contacts. A social identity develops within this network (Azmitia et al., 2008). Emotional support, material aid, services, information, and new social contacts increase personal resources, enhance the ability to cope with change, and influence the course of illnesses (Li & Wu, 2010).

A social network may be small, or it may be large, consisting of numerous

family and community contacts. Contacts can be categorized according to three levels:

1. Level I consists of 6 to 12 people with whom the person has close contact.
2. Level II consists of a larger number of contacts, 30 to 40 people whom the person sees regularly.
3. Level III consists of an even larger number of people with whom a person has direct contact, such as the grocer and mail carrier, and can represent several hundred people.

Each person's social network is slightly different. Multiple contacts allow several networks to interact. Generally, the larger the network, the more support is available. An ideal network structure is fairly dense and interconnected; people within the network are in contact with one another. Dense networks are better able to respond in times of stress and crisis and to provide emotional support to those in distress. For example, residents of a small town are more likely to provide food and shelter to fire victims than neighbors in a large urban area who have little contact with each other.

Ideally, a balance between intense and less intense relationships exists in a social network. When relationships are intense and include only one or two people, the opportunity to interact with other network members is limited. However, isolation can occur without at least a few intense relationships.

Social networks provide opportunities for give and take. Network members both provide and receive support, aid, services, and information. Reciprocity is particularly important because most friendships do not last without the give and take of support and services. A person who is always on the receiving end eventually becomes isolated from others.

Distinguishing a social network from social networking and social media is vital. Because social media has grown in popularity throughout the past two decades, there is controversial evidence about the relationship between social media usage and mental health outcomes (Aalbers et al., 2019). While some studies report that social media use increases stress, depression, and experiencing symptoms of loneliness, others report that abstinence from social media decreases life satisfaction for similar reasons (Aalbers et al., 2019; Vally & D'Souza, 2019).

Social Support

One of the important functions of the social network is to provide **social support** in the form of positive interpersonal interactions as part of a dynamic process that is in constant flux and varies with life events and health status (Whatley et al., 2010). Not all interpersonal interactions within a network are supportive. A person can have a large, complex social network but little social support. Some life events, such as marriage, divorce, and bereavement, actually change the level of social support by adding to or subtracting from a person's social network.

Social support serves three functions:

1. Emotional support contributes to a person's feelings of being cared for or loved.
2. Tangible support provides a person with additional resources.
3. Informational support helps a person view situations in a new light ([Table 19.2](#)).

Social support enhances health outcomes and reduces mortality by helping members make needed behavior changes and buffering stressful life events. Individuals with strong social support have a lower risk of psychopathology related to an increased likelihood of practicing positive and effective coping strategies to deal with stress (McDonald et al., 2020). In a supportive social environment, members feel helped, valued, and in personal control.

Cultural Factors and Ethnic Identity

Cultural expectations and role strain serve as both demands and constraints in the experience of stress. If a person violates cultural group values to meet role expectations, stress occurs; for example, a person may stay in an abusive relationship to avoid the stress of violating a cultural norm that values lifelong marriage, no matter what the circumstances. The potential guilt associated with norm violation and the anticipated isolation from being ostracized seem worse than the physical and psychological pain caused by the abusive situation. Ethnic identity affirmation describes the recognition of positive attributes of one's ethnic group (McDonald et al., 2020). Evidence suggests ethnic identity can help individuals cope with and manage stressful experiences, including chronic stressors (McDonald et al., 2020).

TABLE 19-2: EXAMPLES OF FUNCTIONS OF SOCIAL SUPPORT

Function	Example
Emotional support	Attachment, reassurance, being able to rely on and confide in a person
Tangible support	Direct aid such as loans or gifts, services such as taking care of someone who is ill, doing a job or chore
Informational support	Providing information or advice, giving feedback about how a person is doing

Employment Factors

Employment is another highly valued cultural norm and provides social, psychological, and financial benefits. In all cultures, work is assigned significance beyond economic compensation. It is often the central focus of adulthood and, for many, a source of personal identity. Even if employment brings little real happiness, being employed implies financial needs are being met. Work offers status, regulates life activities, permits association with others, and provides a meaningful life experience. Although work is demanding, unemployment can be equally or more stressful because of the associated isolation, loss of social status, and potential financial strains.

Gender Influences

Gender expectations often become an additional source of demands and constraints for women, who assume multiple roles. In most cultures, women who work outside the home are expected to assume primary responsibility for care of the children and household duties. Maternal employment offers several benefits; however, increased workplace stress and difficulty finding balance between work and family responsibilities can increase the risk of depression in women

(Shepherd-Banigan et al., 2016).

Life Events

In 1967, Holmes and Rahe (1967) presented a psychosocial view of illness by pointing out the complex relationship between life changes and the development of illnesses. They hypothesized that people become ill after they experience major life events, such as marriage, divorce, and bereavement. The more frequent the changes, the greater the possibility of becoming sick. The investigators cited the events that they believed partially accounted for the onset of illnesses and began testing whether these life changes were actual precursors to illness. It soon became clear that not all events have the same effects. For example, the death of a spouse or partner is usually much more devastating and stressful than a change in residence. From their research, the investigators were able to assign relative weights to various life events according to the degree of associated stress. Rahe (1994) devised the Recent Life Changes Questionnaire (Table 19.3) to evaluate the frequency and significance of life-changing events. Numerous research studies subsequently demonstrated the relationship between a recent life change and the severity of near-future illness or the development of a new illness (Friborg, 2019; Rahe, 1994; Rahe et al., 2002). Recent studies show that life changes in older adults that resulted in feeling helpless or fearing for their life reported higher body mass index and more chronic illnesses (Seib et al., 2014). If several life changes occur within a short period, the likelihood that an illness will appear is even greater (Tamers et al., 2014).

TABLE 19-3: RECENT LIFE CHANGES QUESTIONNAIRE

Directions: Sum the life-change units (LCUs) for your life-changing events during the past 12 months.

250–400 LCUs per year: Minor life crisis

Over 400 LCUs per year: Major life crisis

Life Changes LCU Values^a

Family

Death of spouse	105
Marital separation	65
Death of close family member	65
Divorce	62
Pregnancy	60
Change in health of family member	52

Marriage	50
Gain of new family member	50
Marital reconciliation	42
Spouse begins or stops work	37
Son or daughter leaves home	29
In-law trouble	29
Change in number of family get-togethers	26

Personal

Jail term	56
Sex difficulties	49
Death of a close friend	46
Personal injury or illness	42
Change in living conditions	39
Outstanding personal achievement	33
Change in residence	33
Minor violations of the law	32
Begin or end school	32
Change in sleeping habits	31
Revision of personal habits	31
Change in eating habits	29
Change in church activities	29
Vacation	29
Change in school	28
Change in recreation	28
Christmas	26

Work

Fired at work	64
Retirement from work	49
Trouble with boss	39
Business readjustment	38

Change to different line of work	38
Change in work responsibilities	33
Change in work hours or conditions	30
Financial	
Foreclosure of mortgage or loan	57
Change in financial state	43
Mortgage (e.g., home, car)	39
Mortgage or loan less than \$10,000 (e.g., stereo)	26

^a LCU, life-change unit. The number of LCUs reflects the average degree or intensity of the life change. Reprinted with permission from Rahe, R. H. (2000). Recent Life Changes Questionnaire (RLCQ).

RESPONSES TO STRESS

A **stress response** includes simultaneous physiologic and emotional responses. The physiologic stress responses were previously discussed. Emotional responses to stress depend on the significance of the event experience. It is now known that people experience stress differently depending on their gender. Whereas males are more likely to respond to stress with a fight-or-flight response, females have less aggressive responses; they “tend and befriend” (McEwen, 2005).

Emotional Responses

Emotions (psychophysiologic reactions that define a person’s mood) are usually ones of excitement or distress marked by strong feelings and usually accompanied by an impulse toward definite action. If the emotions are intense, a disturbance in intellectual functions occurs. When the situation is viewed as a challenge, emotions are more likely to be positive. If the event is evaluated as threatening or harmful, negative emotions are elicited. Emotions can be categorized as follows:

- *Negative emotions* occur when there is a threat to, delay in, or thwarting of a goal or a conflict between goals: anger, fright, anxiety, guilt, shame, sadness, envy, jealousy, and disgust.

- *Positive emotions* occur when there is movement toward or attainment of a goal: happiness, pride, relief, and love.
- *Borderline emotions* are somewhat ambiguous: hope, compassion, empathy, sympathy, and contentment.
- *Nonemotions* describe emotional reactions that are too ambiguous to fit into any of the preceding categories: confidence, awe, confusion, and excitement (Lazarus, 2006).

TABLE 19-4: CORE RELATIONAL THEMES FOR EACH EMOTION

Emotion	Relational Meaning
Anger	A demeaning offense against me and mine
Anxiety	Facing an uncertain, existential threat
Fright	Facing an immediate, concrete, and overwhelming physical danger
Guilt	Having transgressed a moral imperative
Shame	Having failed to live up to an ego ideal
Sadness	Having experienced an irrevocable loss
Envy	Wanting what someone else has
Jealousy	Resenting a third party for the loss of or a threat to another's affection
Disgust	Taking in or being too close to an indigestible object or idea (metaphorically speaking)
Happiness	Making reasonable progress toward the realization of a goal
Pride	Enhancement of one's ego identity by taking credit for a valued object or achievement, either our own or that of someone or a group with whom we identify
Relief	A distressing goal/incongruent condition that has changed for the better or gone away
Hope	Fearing the worst but yearning for better
Love	Desiring or participating in affection, usually but not necessarily reciprocated
Compassion	Being moved by another's suffering and wanting to help

Emotions are expressed as themes that summarize dangers or benefits of each

stressful situation. For instance, physical danger provokes fear; a loss leads to feelings of sadness (Table 19.4). Emotions have their own innate responses that are automatic and unique; for example, anger may automatically provoke tremors in one person but both tremors and perspiration in another. Emotions often provoke impulsive behavior. For example, the first impulse of a young musician facing his first performance at Carnegie Hall who experiences stage fright is to run home. As he resists this impulse, he begins coping with his fears in order to perform.

COPING

Coping is a deliberate, planned, and psychological effort to manage stressful demands. The coping process may inhibit or override the innate urge to act. Positive coping leads to adaptation, which is characterized by a balance between health and illness, a sense of well-being, and maximum **social functioning**. When a person does not cope well, maladaptations occur that can shift the balance toward illness, a diminished self-concept, and deterioration in social functioning.

KEYCONCEPTS Coping is a deliberate, planned, and psychological effort to manage stressful demands.

There are two types of coping. In **problem-focused coping**, the person addresses the source of stress and solves the problem (eliminating it or changing its effects). In **emotion-focused coping**, the person reduces the stress by reinterpreting the situation to change its meaning (Boxes 19.3 and 19.4).

Different coping strategies will be needed for different situations. Over time, strategies become automatic and develop into patterns for each person. Some situations require a combination of strategies and activities. Ideally, a stressful situation is matched with the needed resources as the events are unfolding. Social support can be critical in helping people cope with difficult situations. Successful coping with life stresses is linked to quality of life and to physical and mental health (Lazarus, 2001).

As a part of the coping process, reappraisal is important because of the changing nature of the stressful situation. **Reappraisal**, which is the same as appraisal except that it happens after coping strategies are implemented, provides

feedback about the outcomes and allows for continual adjustment and actions to new information.

BOX 19.3

Ways of Coping: Examples of Problem-Focused Versus Emotion-Focused Coping

Problem-Focused Coping

- When noise from the television interrupts a student's studying and causes the student to be stressed, the student turns off the television and eliminates the noise.
- An abused spouse is finally able to leave her husband because she realizes that the abuse will not stop even though he promises never to hit her again.

Emotion-Focused Coping

- A husband is adamantly opposed to visiting his wife's relatives because they keep dogs in their house. Even though the dogs are well cared for, their presence in the relative's home violates his need for an orderly, clean house and causes the husband sufficient stress that he copes with by refusing to visit. This becomes a source of marital conflict. One holiday, the husband is given a puppy and immediately becomes attached to the dog, who soon becomes a valued family member. The husband then begins to view his wife's relatives differently and willingly visits their house more often.
- A mother is afraid that her teenage daughter has been in an accident because she did not come home after a party. Then, the woman remembers that she gave her daughter permission to stay at a friend's house. She immediately feels better.

BOX 19.4

Research for Best Practice: Emotion- Versus Problem-Focused Coping for Health Threats

del-Pino-Casado, R., Pérez-Cruz, M., & Frías-Osuna, A. (2014). Coping, subjective burden and anxiety among family caregivers of older dependent. Journal of Clinical Nursing, 23, 3335–3344.

THE QUESTION: Do stressors, coping, and subjective burden contribute to anxiety in caregivers?

METHODS: Data from 140 family caregivers were analyzed using descriptive statistics, correlation coefficients, and path analysis. Sociodemographic data and several scales were used to collect data.

FINDINGS: Stressors, coping, emotion-focused coping, dysfunctional coping, and subjective burden were related to greater anxiety.

IMPLICATIONS FOR NURSING: Stressors, dysfunctional coping, and subjective burden can be used in clinical practice for early detection of and early intervention for anxiety. Problem solving, positive reappraisal, assertiveness, and control of negative thoughts may not be as effective in reducing anxiety.

ADAPTATION

Adaptation can be conceptualized as a person's capacity to survive and flourish (Lazarus, 2006). Adaptation or lack of it affects three important areas: health, psychological well-being, and social functioning. A period of stress may compromise any or all of these areas. If a person copes successfully with stress, they return to a previous level of adaptation. Successful coping results in an improvement in health, well-being, and social functioning. Unfortunately, coping strategies will not always be successful and maladaptation occurs.

KEYCONCEPTS **Adaptation** is a person's capacity to survive and flourish. Adaptation affects three important areas: health, psychological well-being, and social functioning.

It is impossible to separate completely the adaptation areas of health, well-being, and social functioning. A maladaptation in any one area can negatively affect the others. For instance, the appearance of psychiatric symptoms can cause problems in performance in the work environment that in turn elicit a negative self-concept. Although each area will be discussed separately, the reader should realize that when one area is affected, most likely all three areas are affected.

Healthy Coping

Health can be negatively affected by stress when coping is ineffective and the damaging condition or situation is not ameliorated or the emotional distress is not regulated. Examples of ineffective coping include using emotion-focused coping when a problem-focused approach is appropriate, such as if a woman reinterprets an abusive situation as her fault instead of getting help to remove herself from the environment. In addition, if a coping strategy violates cultural norms and lifestyle, stress is often exaggerated. Some coping strategies actually increase the risk for mortality and morbidity, such as the excessive use of alcohol, drugs, or tobacco. Many people use overeating, smoking, or drinking to reduce stress. They may feel better temporarily but are actually increasing their risk for illness. For people whose behaviors exacerbate their illnesses, learning new behaviors becomes important. Healthy coping strategies such as exercising and obtaining adequate sleep and nutrition contribute to stress reduction and the

promotion of long-term health.

Psychological Well-Being

An ideal outcome to a stress response is feeling good about how stress is handled. Outcome satisfaction for one person does not necessarily represent outcome satisfaction for another. For example, suppose that two students receive the same passing score on an examination. One may feel a sense of relief, but the other may feel anxious because he appraises the score as too low. Understanding a person's emotional response to an outcome is essential to analyzing its personal meaning. People who consistently have positive outcomes from stressful experiences are more likely to have positive self-esteem and self-confidence. Unsatisfactory outcomes from stressful experiences are associated with negative mood states, such as depression, anger, guilt leading to decreased self-esteem, and feelings of helplessness. Likewise, if the situation was appraised as challenging rather than harmful or threatening, increased self-confidence and a sense of well-being are likely to follow. If the situation was accurately appraised as harmful or threatening but viewed as manageable, the outcome may also be positive.

Social Functioning

Social functioning, the performance of daily activities within the context of interpersonal relations and family and community roles, can be seriously impaired during stressful episodes. For instance, a student who is experiencing the stress of needing to pass an examination to satisfactorily pass a class may not be able to maintain social relationships or keep up with work-related responsibilities satisfactorily. Social functioning continues to be impaired if the person views the outcome as unsuccessful and experiences negative emotions. If successful coping with a stressful encounter leads to a positive outcome, social functioning returns to normal or is improved.

NURSING CARE FOR THE PERSON

EXPERIENCING STRESS

The overall goals in the nursing care of the person experiencing stress are to resolve the stressful person–environment situation, reduce the physiologic and psychological stress response, and develop positive coping skills. The goals for those who are at high risk for stress (experiencing recent life changes, vulnerable to stress, or have limited coping mechanisms) are to recognize the potential for stressful situations and strengthen positive coping skills through education and practice.

Stress responses vary from one person to another. Acute stress is easier to recognize than chronic stress. In many instances, living with chronic stress has become a way of life and is no longer recognized. If there are significant emotional or behavioral symptoms in response to an identifiable stressful situation, a diagnosis of adjustment disorder may be made (American Psychiatric Association, 2013). From the assessment data, the nurse can determine any illnesses, the intensity of the stress response, and the effectiveness of coping strategies. Nurses typically identify stress responses in people or family members who are receiving treatment for other health problems.

Telehealth and web-based stress management programs offer promising treatment options for individuals who experience stress. For example, college students are known to experience high levels of stress; however, they rarely seek treatment for a number of reasons such as accessibility and social stigma (Coudray et al., 2019). Web-based programs have been found to be helpful for students experiencing distress (Coudray et al., 2019). Further, the use of telehealth programs have been implemented to assist with mental health care for military personnel experiencing posttraumatic stress disorder with success (Engel et al., 2016). These programs may be instrumental in assisting individuals experiencing to seek guidance from health care professionals.

Mental Health Nursing Assessment

The assessment of a person experiencing stress should include a careful health history, current stressful event, and coping resources. If a psychiatric disorder is present, symptoms may spontaneously reappear even when no alteration has occurred in the patient's treatment regimen.

Physical Assessment

Review of Systems

A systems review can help the nurse identify the person's own unique physiologic response to stress and can also provide important data on the effect of chronic illnesses. These data are useful for understanding the person–environment situation and the person's stress reactions, coping responses, and adaptation.

Physical Functioning

Physical functioning usually changes during a stress response. Typically, sleep is disturbed, appetite either increases or decreases, body weight fluctuates, and sexual activity changes. Physical appearance may be uncharacteristically disheveled—a projection of the person's feelings. Body language expresses muscle tension, which conveys a state of anxiety not usually present. Because exercise is an important strategy in stress reduction, the nurse should assess the amount of physical activity, tolerance for exercise, and usual exercise patterns. Determining the details of the person's exercise pattern and any recent changes can help in formulating reasonable interventions.

Pharmacologic Assessment

In assessing a person's coping strategies, the nurse needs to ask about the use of alcohol, tobacco, marijuana, and any other addictive substances. Many people begin or increase the frequency of using these substances as a way of coping with stress. In turn, substance abuse contributes to the stress behavior. Knowing details about the person's use of these substances (number of times a day or week, amount, circumstances, side effects) helps in determining the role these substances play in overall stress reduction or management. The more important the substances are in the person's handling of stress, the more difficult it will be to change the addictive behavior.

Stress also often prompts people to use antianxiety medication without supervision. Use of over-the-counter and herbal medications is also common. The nurse should carefully assess the use of any drugs or herbal remedies used to

manage stress symptoms. If drugs are the primary coping strategy, further evaluation is needed with a possible referral to a mental health specialist. If a psychiatric disorder is present, the nurse should assess medication adherence, especially if the psychiatric symptoms are reappearing.

Psychosocial Assessment

Unlike assessment for other mental health problems, psychological assessment of the person under stress does not ordinarily include a mental status examination. Instead, psychological assessment focuses on the person's emotions and their severity, as well as their coping strategies. The assessment elicits the person's appraisal of risks and benefits, the personal meaning of the situation, and the person's commitment to a particular outcome. The nurse can then understand how vulnerable the person is to stress.

Using therapeutic communication techniques, a person's emotional state is assessed in a nurse–patient interview. By beginning the interview with a statement such as, “Let's talk about what you have been feeling,” the nurse can elicit the feelings that the person has been experiencing. Identifying the person's emotions can be helpful in assessing the intensity of the stress being experienced. Negative emotions (anger, fright, anxiety, guilt, shame, sadness, envy, jealousy, and disgust) are usually associated with an inability to cope and severe stress.

After identifying the person's emotions, the nurse determines how the person reacts initially to them. For example, does the person who is angry respond by carrying out the innate urge to attack someone whom the person blames for the situation? Or does that person respond by thinking through the situation and overriding the initial innate urge to act? The person who tends to act impulsively has few real coping skills. For the person who can resist the innate urge to act and has developed coping skills, the focus of the assessment becomes determining their effectiveness.

In an assessment interview, it can be determined whether the person uses problem-focused or emotion-focused coping strategies effectively. Problem-focused coping is effective when the person can accurately assess the situation. In this case, the person sets goals, seeks information, masters new skills, and seeks help as needed. Emotion-focused coping is effective when the person has inaccurately assessed the situation and coping corrects the false interpretation.

Social assessment data are invaluable in determining the person's resources for positive coping. The ability to make healthy lifestyle changes is strongly influenced by the person's health beliefs and family support system. Even the expression of stress is related to social factors, particularly cultural expectations and values.

Assessment could include the use of the Recent Life Changes Questionnaire (refer to [Table 19.3](#)) to determine the number and importance of life changes that the patient has experienced within the past year. If several recent life changes have occurred, the person–environment relationship has changed. The person is likely to be either at high risk for or already experiencing stress.

The assessment should include identification of the person's social network. Because employment is the mainstay of adulthood and the source of many personal contacts, assessment of any recent changes in employment status is important. If a person is unemployed, the nurse should determine the significance of the unemployment and its effects on the person's social network. For children and young adults, nurses should note any recent changes in their attendance at school. The nurse should elicit the following data:

- Size and extent of the patient's social network, both relatives and nonrelatives, professional and nonprofessional, and how long known
- Functions that the network serves (e.g., intimacy, social integration, nurturance, reassurance of worth, guidance and advice, access to new contacts)
- Degree of reciprocity between the patient and other network members; that is, who provides support to the patient and who the patient supports
- Degree of interconnectedness; that is, how many of the network members know one another and are in contact

Priorities of Nursing Care

There are several possible priorities of nursing care depending upon the individual's response to stress. For patients with changes in eating, sleeping, or activity, the priorities of care can focus on reestablishing these functional patterns. For other patients, the priorities may focus on psychological issues such as low self-esteem, fear, and hopelessness. Other patients may not have the psychological resources to cope with the situation, which will lead to a focus on

coping skills.

Nursing Interventions

People under stress can usually benefit from approaches supporting healthy behaviors. Activities of daily living are usually interrupted, and the affected individuals often feel that they have no time for themselves. The stressed person who is normally well groomed and dressed may appear disheveled and unkempt. Simply reinstating the daily routine of shaving or combing hair can improve the person's outlook on life and ability to cope with the stress.

Stress is commonly manifested in the areas of nutrition and activity. During stressful periods, a person's eating patterns change. To cope with stress, a person may either overeat or become anorexic. Both are ineffective coping behaviors and actually contribute to stress. Educating the patient about the importance of maintaining an adequate diet during the period of stress will highlight its importance. It will also allow the nurse to help the person decide how eating behaviors can be changed.

Exercise can reduce the emotional and behavioral responses to stress. In addition to the physical benefits of exercise, a regular exercise routine can provide structure to a person's life, enhance self-confidence, and increase feelings of well-being. People who are stressed are often not receptive to the idea of exercise, particularly if it has not been a part of their routine. Exploring the patient's personal beliefs about the value of activity will help to determine whether exercise is a reasonable activity for that person.

The person under stress tends to be tense, nervous, and on edge. Simple relaxation techniques help the person relax and may improve coping skills. If these techniques do not help the patient relax, distraction or guided imagery may be taught to the patient (see [Chapter 10](#)). In some instances, spiritually oriented interventions can be used. Referral to a mental health specialist for hypnosis or biofeedback should be considered for patients who have severe stress responses.

Psychosocial Nursing Interventions

Numerous interventions help reduce stress and support coping efforts. All of the

interventions are best carried out within the framework of a supportive nurse–patient relationship.

Problem Solving

Assisting patients to develop appropriate problem-solving strategies based on personal strengths and previous experiences is important in understanding and coping with stressful situations. Some aspects of any situation cannot be changed, such as a family member's illness or a death of a loved one, but usually there are areas within the patient's control that can be changed. For example, a caregiver cannot reverse the family member's disability, but can arrange for short-term respite.

Encouraging patients to examine times when coping has been successful and examine aspects of that situation can help in identifying strengths and strategies for the current problem. For example, a young mother was completely overwhelmed with feelings of inadequacy after the birth of her third child. Further assessment revealed that the patient's mother had helped during the 6 weeks after the other children had been born. The patient's mother was not available for the third birth. First, the nurse acknowledged and validated that having three children could be overwhelming for anyone. The nurse also explained the postpartum hormonal changes that were occurring, validating that the patient's feelings were typical of many mothers. Finally, together, the nurse and the patient identified resources in her environment that could support her during the postpartum period.

Family Interventions

People who are coping with stressful situations can often benefit from interventions that facilitate family unit functioning and promote the health and welfare of all family members. To intervene with the total family, the stressed person must agree for the family members to be involved. If the data gathered from the assessment of supportive and unsupportive factors indicate that the family members are not supportive, the nurse should assist the patient to consider expanding their social network. If the family is the major source of support, the nurse should design interventions that support the functioning of the family unit. Parent education can also be effective in supporting family unit

functioning. If family therapy is needed, the nurse should refer the family to an advanced practice specialist.

Evaluation and Treatment Outcomes

The treatment outcomes established in the initial plan of care guide the evaluation. Individual outcomes relate to improved health, well-being, and social function. Depending on the level of intervention, there can also be family and network outcomes. Family outcomes may be related to improved communication or social support; for instance, caregiver stress is reduced when other members of the family help in the care of the ill member. Social network outcomes focus on modifying the social network to increase support for the individual.

SUMMARY OF KEY POINTS

- Stress affects everyone. Coping with stress can produce positive and negative outcomes. The person can learn and grow from the experience or maladaptation can occur.
- The concept of homeostasis is the body's tendency to resist physiologic change and hold bodily functions relatively consistent, well-coordinated, and usually stable.
- When the brain interprets an event as a threat, physiologic stability is challenged, and a "fight-or-flight" response occurs.
- Allostasis describes a dynamic regulatory process that maintains homeostasis through a process of adaptation. Physiologic stability is achieved when the autonomic nervous system, the HPA, and the cardiovascular, metabolic, and immune systems respond to internal and external stimuli. As wear and tear on the brain and body occur, there is a corresponding increase in the number of abnormal biologic parameters called the AL. AL is an indication of chronic stress.
- Stress is defined as an environmental pressure or force that puts strain on a

person's system. Acute stress can lead to physiologic overload, which in turn can have a negative impact on a person's health, well-being, and social functioning. Chronic stress is associated with AL that can lead to negative health outcomes.

- Stress responses are determined by the interaction with environment and the individual's cognitive appraisal of the risks and benefits of a situation. Stress responses are simultaneously emotional and physiologic, leading to an innate tendency to act.
- Many personal factors, such as personality patterns, beliefs, values, and commitment to an outcome, interact with environmental demands and constraints that produce a person–environment relationship.
- Effective coping can be either problem focused or emotion focused. The outcome of successful coping is adaptation through enhanced health, psychological well-being, and social functioning.
- Within the social network, social support can help a person cope with stress.
- The overall goals in the nursing management of stress are to resolve the stressful person–environment situation, reduce the stress response, and develop positive coping skills.

Unfolding Patient Stories: David Carter

Part 2

Recall from [Chapter 12](#) David Carter, age 28 with schizophrenia who was hospitalized after a

violent outburst having paranoid delusions and auditory hallucinations. He lives with his mother and previously worked as a grocery clerk. What can be influencing his increased social isolation? What factors should the nurse consider when developing a plan of care for discharge to promote David's social functioning and lessen his isolation?

CRITICAL THINKING CHALLENGES

1. Compare and contrast the concepts of homeostasis and allostasis.
2. Discuss the impact of acute stress versus chronic stress. Why is chronic stress

of more concern than acute stress?

3. Explain why one person may experience the stress of losing a job differently from another.
4. An individual is experiencing being overweight, has hypertension and insomnia, and was recently widowed. The doctor has told them to lose weight and quit smoking. The individual seeks your advice. Would you recommend a problem-focused or an emotion-focused approach?
5. A person at the local shelter announced to the group that they were returning to their partner because it was partly their fault that their partner beat them. Is this an example of problem-focused or emotion-focused coping? Justify your answer.
6. **Unfolding Patient Stories: David Carter** Using the Stress Coping and Adaptation Model (see [Fig. 19.2](#)), assess a patient and determine the cognitive appraisal of significant events.

Movie Viewing Guides

Noise:(2007). David Owen (Tim Robbins) copes with the stressful noises of the city, specifically car alarms, by becoming aggressive and destructive. At first, the noise is merely an irritant. Later, he interprets the noise as an assault on everyone. He becomes an activist, protecting others, and gradually becomes very grandiose. As his grandiosity increases, he becomes more and more driven to damage vehicles with active car alarms.

VIEWING POINTS: What is the relationship between the physiologic response to the noise and his eventual grandiose behavior? How would you help him reduce the stressful experience and cope positively? Observe your own feelings throughout the movie. Did you experience stress?

Management of Anger, Aggression, and Violence

Sandra P. Thomas

KEYCONCEPTS

- anger
- aggression
- gender, culture, and ethnic differences
- intervention fit

- violence

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Explore the difference between healthy and maladaptive styles of anger.
2. Discuss principles of anger management as a psychoeducational intervention to promote wellness.
3. Discuss the factors that influence aggressive and violent behaviors.
4. Discuss theories used to explain anger, aggression, and violence.
5. Identify behaviors or actions that escalate and de-escalate violent behavior.
6. Recognize the risk for verbal and physical attacks on nurses.
7. Generate options for responding to the expression of anger, aggression, and violent behaviors in clinical nursing practice.
8. Apply the nursing process to the management of anger, aggression, and violence in patients.

KEY TERMS

- Anger management
- Catharsis
- Instrumental aggression
- Inwardly directed anger
- Maladaptive anger
- Outwardly directed anger

INTRODUCTION

Maladaptive anger and potentially lethal violent behavior are increasingly evident in contemporary Western society. Temper tantrums of athletes, episodes of road rage, and school shootings often dominate the evening news and social media. Clearly, mismanagement of angry emotion is a serious social problem.

Language pertaining to anger is imprecise and confusing. Some of the words used interchangeably with anger include *annoyance*, *frustration*, *temper*, *resentment*, *hostility*, *hatred*, and *rage*. To avoid perpetuating the confusion, three key concepts were selected for use in this chapter: *anger*, *aggression*, and *violence*. Anger, aggression, and violence should not be viewed as a continuum

because one does not necessarily lead to another. That is a myth. Cultural myths about anger abound (Table 20-1).

One goal of this chapter is to dispel confusion between anger as a normal, healthy response to violation of one's integrity and maladaptive anger that is detrimental to one's mental and physical health. Understanding this distinction is an important aspect of emotional intelligence.

Table 20-1: Cultural Myths about Anger

Myth

Anger is a knee-jerk reaction to external events.

Anger can be uncontrollable, resulting in crimes of passion such as “involuntary manslaughter.”

Anger behavior in adulthood is determined by temperament and childhood experiences.

Men are angrier than women.

People must behave aggressively to get what they want.

A second goal of this chapter is to outline risk factors for aggression and violence and describe preventive interventions, particularly as they pertain to the psychiatric nursing care environment. Verbal and physical aggression and violence also occur across a wide spectrum of other health care settings, including emergency departments, medical–surgical facilities, and primary care. All nurses must develop expertise in prevention and management of aggression. Contrary to a popular misconception, patients who have psychiatric problems are not more violent than other patients, but astute clinicians need to know which patients *might* become aggressive given a combination of known risk factors with specific environmental conditions.

ANGER

Anger is an internal affective state, usually temporary rather than an enduring hostile attitude. If expressed outwardly, anger behavior can be constructive or destructive. Whereas destructive anger alienates other people and invites retaliation, constructive anger can be a powerful force for asserting one's rights

and achieving social justice.

Anger is a signal that something is wrong in a situation; thus, the angry individual has the urge to act. The situation is more distressing than a minor annoyance such as a slow grocery line. An interpersonal offense such as unjust or disrespectful treatment (a spouse lying, a coworker taking advantage) often provokes anger. The meaning of an angry episode depends on the relational context. For example, anger is more intense and intermingled with considerable hurt when loved ones violate the implicit relational contract (“If he loved me, how could he lie about that? How can I trust him again?”) (Thomas, 2006).

KEY CONCEPT Anger is “a strong, uncomfortable emotional response to a provocation that is unwanted and incongruent with one’s values, beliefs, or rights” (Thomas, 2001).

Maladaptive anger: While anger arousal is normal, anger becomes maladaptive when it is too frequent, too intense, or managed in unhealthy ways: excessive outward expression (e.g., losing temper, yelling) or suppression (i.e., seething inside and ruminating about grievances). Maladaptive anger is linked to psychiatric conditions as well as a plethora of medical conditions. For example, anger and hostility are associated with hospitalizations in patients with heart failure (Endrighi et al., 2019), and *excessive outwardly directed anger* is linked to coronary heart disease (Pimple et al., 2019), metabolic syndrome (Thomas et al., 2020), and myocardial infarction (Buckley et al., 2015; Smeijers et al., 2015). *Suppressed anger* is related to arthritis, breast and colorectal cancer, chronic pain, and hypertension (Kakoo Briosio et al., 2020; Russell et al., 2016; Sommer et al., 2019) and is a risk factor for postpartum depression (Bruno et al., 2017).

In contrast to these maladaptive **anger management** styles, research shows that anger discussed with other people in a constructive way and mindfulness-based stress reduction have a beneficial effect on blood pressure (Lee et al., 2020; Momeni et al., 2016; Thomas, 1997a), as well as statistically significant associations with better general health, a higher sense of self-efficacy, less depression, and a lower likelihood of obesity (Thomas, 1997b). Anger controlled through calming strategies is associated with faster wound healing and other health benefits (Barlow et al., 2019; Gouin et al., 2008). Thus, effective anger management is important in maintenance of emotional wellness and holistic health (Troost et al., 2017).

Skillful anger control is also essential to social and occupational success.

People with poor anger control have more conflict at work, change jobs more frequently, take more unwise risks, and have more accidents than people with adaptive anger behavior (Halperin & Reifen Tagar, 2017).

The Experience of Anger

When you are angry, your heart pounds, your blood pressure rises, you breathe faster, your muscles tense, and you clench your jaw or fists as you experience an impulse to do something with this physical energy. Some individuals experience anger arousal as pleasurable, but others find its strong physical manifestations scary and unpleasant. People who were taught that anger is a sin may immediately try to ban it from awareness and deny its existence. However, suppression actually results in greater, more prolonged physiological arousal. A better option is finding a way to safely release the physical energy, either through vigorous physical activity (e.g., jogging) or through a calming activity (e.g., deep breathing). Later, at an opportune time, calmly discussing the incident with the provocateur permits clarification of misunderstandings and resolution of grievances. [Box 20-1](#) invites the reader to explore variations in anger experience.

BOX 20.1

Self-Awareness Exercise: Personal Experience of Anger

People's reactions differ when they experience anger. Some people report a sense of power, control, and calmness different from their usual experience; others report feeling shaky, tearful, and on the verge of collapse. Still others describe physical sensations of nausea and dizziness.

Think about the last time you felt angry. List the body sensations and other emotions that you experienced. Now ask a friend, colleague, or family member to do the same. Compare lists. What are the similarities and differences between you? How will awareness of these differences help you in your clinical practice?

The physiology of anger involves the cerebral cortex, the sympathetic nervous system, the adrenal medulla (which secretes adrenaline and noradrenaline), the adrenal cortex (which secretes cortisol), the cardiovascular system, and even the immune system. From a biologic viewpoint, angry episodes may partially originate from developmental deficits, anoxia, malnutrition, toxins, tumors, neurodegenerative diseases, or trauma affecting the brain.

The Expression of Anger

While the physiological arousal of anger is similar in all people, ways of expressing anger differ. The most common modes, or styles, of anger expression are listed in [Table 20-2](#).

In Western culture, control of anger was the dominant stance from Greco-Roman times to the 20th century. Anger was viewed as sinful, dangerous, and destructive—an irrational emotion to be contained, controlled, and denied. This pejorative view contributed to the development of a powerful taboo against feeling and expressing anger. People who have accepted this persistent taboo may have difficulty even knowing when they are angry. They may use euphemisms such as “a little upset” (Rubin, 1970).

In contrast to the denial or containment of angry emotion, some mental health care providers began to advocate the use of **catharsis** during the early 20th century, based on the animal research of ethologists and on Freud’s conceptualization of “strangled affect”; rather than holding in their anger, people were urged to “vent it,” lest there be a dangerous “slush fund” of unexpressed anger building up in the body (Rubin, 1970). The legacy of the ill-advised “ventilationist movement” is still with us, visible in rude, uncivil behavior in the nation’s classrooms, offices, roadways, and other public places, as well as in countless homes where loud arguments are a daily occurrence.

Table 20-2: STYLES OF ANGER EXPRESSION

Style	Characteristic Behaviors
Anger suppression	Feeling anxious when anger is aroused Acting as though nothing happened Withdrawing from people when angry Conveying anger nonverbally by body language Sulking, pouting, or ruminating
Unhealthy outward anger expression	Flying off the handle Expressing anger in an attacking or blaming way Yelling, saying nasty things Calling the other person names or using profanity Using fists rather than words to express angry feelings
Constructive anger	Discussing the anger with a friend or family member even if

discussion	<p>the provocateur cannot be confronted at the time</p> <p>Approaching the person with whom one is angry and discussing the concern directly</p> <p>Using “I” language to describe feelings and request changes in another’s behavior</p>
------------	---

More ideally, the clear expression of honest anger may prevent aggression and help to resolve a situation (Thomas, 2009). Suppression of anger, prolonged rumination about the grievance, and malevolent fantasies of revenge do not resolve a problem and may result in negative consequences later. Similarly, antagonistic anger toward an intimate partner or coworker only exacerbates the conflict (Sommer et al., 2016). In contrast, if anger is expressed assertively, beneficial outcomes are possible. In Averill’s classic study (1983) of everyday anger, 76% of those who were on the receiving end of someone else’s anger reported that they recognized their own faults as a result of the anger incident. Contrary to popular misconception, the relationship with the angry person was strengthened, not weakened.

Special Issues in the Nurse–Patient Relationship

Nurses may withdraw from angry patients and try to hide their own anger because “good nurses” do not get angry at patients. Coldness and distancing on the part of staff are acutely painful to patients (Jalil & Dickens, 2018). What patients want are steady, dependable, confident caregivers who will remain connected with them when they are angry.

Nurses’ perceptions and beliefs about themselves as individuals and professionals influence their response to aggressive behaviors. For example, a nurse who considers any expression of anger inappropriate will approach an agitated patient differently from a nurse who considers agitated behavior to be meaningful. Understandably, nurses often shrink from patient anger when their own family backgrounds have been characterized by out-of-control anger or abuse. A nurse who has previously been assaulted by a patient is also more likely to have difficulty dealing with subsequent episodes of aggression ([Box 20-2](#)).

Some patients have an uncanny ability to target a nurse’s vulnerable characteristics. Although it is normal to become defensive when feeling vulnerable, maintaining personal control is a must. If not, the potential for

punitive interventions is greater. Threatening an agitated patient (e.g., “You are going to get an injection if you don’t calm down.”) will only worsen a volatile situation. Nurses must collaborate with other members of the treatment team when interacting with particularly challenging patients, obtaining consultation from supervisors if necessary.

Assessment of Anger

Both **outwardly directed anger** (particularly the hostile, attacking forms) and **inwardly directed anger** (i.e., anger that is stifled despite strong arousal) produce adverse consequences, indicating a need for anger management intervention. Complicating matters, however, most people’s anger styles cannot be neatly categorized as “anger-in” or “anger-out” because they behave differently in different environments (e.g., yelling at assistants in the office, stifling anger at a family member). Therefore, it is necessary to conduct a careful assessment of a patient’s behavior pattern across various situations.

BOX 20.2

Research for Best Practice: Mental Health Nurses’ Emotions and Exposure to Patient Aggression

Jalil, R., Huber, J. W., Sixsmith, J., & Dickens, G. S. (2018). *Mental health nurses’ emotions, exposure to patient aggression attitudes to and use of coercive measures: Cross-sectional questionnaire survey*. *International Journal of Nursing Studies*, 75, 130–138. <https://doi.org/10.1016/j.ijnurstu.2017.07.018>

THE QUESTION: What are the relationships between mental health nurses’ exposure to patient aggression and their emotions/attitudes toward coercive containment measures and involvement in patient seclusion and restraint?

METHODS: Sixty-eight mental health nurses completed a questionnaire about their exposure to aggression, their attitudes toward seclusion and restraint, and their emotions.

FINDINGS: Verbal aggression that is targeted, demeaning, or humiliating is associated with higher experienced anger provocation and approval of restraints or seclusion, but anger did not predict involvement in the use of restraints or seclusion.

IMPLICATIONS FOR NURSING: Nurses may benefit from interventions that improve their skill and coping strategies for dealing with verbal aggression. Nurses should be sufficiently self-aware to avoid using restraints or seclusion when experiencing anger.

The manner of anger expression is not the only important aspect of

assessment. The difficulty in regulating the frequency and intensity of anger also must be assessed. Intense anger, evident in clenched fists and readiness to burst when arguing with others, can even trigger a heart attack (Buckley et al., 2015). Having an episode of intense anger caused an 8.5-fold increase in risk of acute coronary occlusion within the next 2 hours. The extent to which anger is creating problems at work or intimate relationships should be evaluated, as well as the use of unhealthy coping techniques such as binge eating, drinking, or medicating their angry distress with over-the-counter or illicit drugs (Feinson & Hornik-Lurie, 2016; Thomas, 2006). Evidence-based practice has been extensively used with thousands of people, permitting comparison of a client with established norms. The Spielberger State-Trait Anger Expression Inventory is one such tool (Spielberger, 1999). This instrument measures the general temperamental proneness to be aroused to anger (trait anger) as well as current feelings (state anger) and several styles of anger expression, including anger-in, anger-out, and control through calming techniques.

Because anger and aggression can be symptomatic of many underlying psychiatric or medical disorders, from posttraumatic stress disorder and bipolar disorder to toxicities and head injuries, first any underlying disorder must be properly evaluated. Only one anger-related disorder, intermittent explosive disorder (IED), appears in the *Diagnostic and Statistical Manual of Mental Disorders* (American Psychiatric Association [APA], 2013). This diagnosis is used when recurring aggressive outbursts cannot be attributed to any other condition. People with IED display aggressive behavior that is disproportionate to the precipitating event, usually a minor provocation by a family member or other close associate (APA, 2013).

Once thought to be rare, more recent research has shown that IED is as common as many other psychiatric disorders (Coccaro, 2019). The disorder usually appears during the teen years and persists over the life course. A national study indicates that the average number of lifetime anger attacks per person is large (43 per person). Because the disorder involves inadequate production or functioning of serotonin, IED is commonly treated with selective serotonin reuptake inhibitors (Coccaro & Lee, 2019). However, behavior therapy should also be included. Very few people with IED ever choose to be treated for their anger (Rynar & Coccaro, 2018) although the IED population is responsive to treatment (Galbraith et al., 2018).

Culture and Gender Considerations in Assessment

Anger is one of the six universal emotions with identifiable facial features and emotionally inflected speech. People across the globe experience the emotion of anger, along with the impulse to act, but culture is perhaps the most important determinant of what angry individuals actually do. Cultural differences in anger behavior can emanate from the historical trajectories, religions, languages, and customs of a group of people (Thomas, 2006). The same event can provoke very different emotional responses in culturally different persons (e.g., a random act of greeting such as a smile by a stranger could be perceived as insulting by one individual but dismissed with a laugh by someone from another culture).

KEYCONCEPT Gender, culture, and ethnic differences in the experience and expression of anger must be taken into consideration before planning interventions.

Gender role socialization influences beliefs about the appropriateness of “owning” angry emotionality and revealing it to others. In Western cultures, aggressive behavior has traditionally been expected in males and more conciliatory behavior expected in females (see [Table 20-2](#)). However, these generalizations may not apply to marginalized underrepresented groups or sexual orientation and gender identification (e.g., individuals who identify as lesbian, gay, bisexual, transgender, and queer or questioning). Some Eastern cultures disapprove of anger for both genders, particularly cultures emphasizing connectedness rather than individualism (e.g., Japanese). Therefore, clients in such cultures may ruminate for lengthy periods about anger episodes rather than verbalizing their feelings. The influence of cultural context was evident in a cross-cultural study showing that greater outward expression of anger actually *reduced* cardiovascular risk in Japanese individuals, while increasing cardiovascular risk in Americans (Kitayama et al., 2015). A more extensive discussion of culture and gender factors can be found in Thomas (2006).

The essential element in a cultural assessment is exploration of what the client learned about anger and its display in their culture and family of origin (the primary bearer of that culture). For example, African Americans may have been taught as children to suppress anger at racist discrimination, but suppression can increase their risk for depression and hypertension; in adulthood, anger at societal racism is one of the main reasons that African Americans seek therapy (Kelly, 2019). Therapy must be tailored in a culturally responsive manner.

Anger Interventions

There are self-regulation and communication techniques that promote the management of anger in nondestructive ways. However, most people lack skill in handling anger constructively. Few people have healthy role models to observe while growing up. Education in anger management can be valuable, both for psychological growth and improved interpersonal relations (Trost et al., 2017).

Anger Management: A Psychoeducational Intervention to Promote Wellness

Anger management is an effective intervention that nurses can deliver to persons whose anger behavior is maladaptive in some way (i.e., interfering with success in work or relationships) but *not violent*. In recent years, there has been an increase in court-mandated “anger management” for persons whose behavior is violent as opposed to angry. When these individuals do not greatly benefit, a conclusion may be drawn that anger management is ineffective. However, psychoeducational anger management courses cannot be expected to modify *violent* behavior. (Interventions designed for aggressive and violent individuals are presented later in the chapter.)

The desired outcomes of any anger management intervention are to teach people to (1) effectively modulate the physiological arousal of anger, (2) alter any irrational thoughts fueling the anger, and (3) modify maladaptive anger behaviors (e.g., blaming, attacking, or suppressing) that prevent problem-solving in daily living. Group work is valuable to anger management clients because they need to practice new behaviors in an interpersonal context that offers feedback and support. The leader of an anger management group functions as a teacher and coach, not as a therapist. Potential participants should be screened and referred to individual counseling or psychotherapy if their anger is chronic. Some individuals have deeper developmental issues that mitigate against their successful participation in anger management groups (Shepherd & Cant, 2020). Exclusion criteria are paranoia, organic disorders, and severe personality disorders (Thomas, 2001). Candidates for psychoeducational anger management

classes must have some insight that their behavior is problematic and some desire to enlarge their behavioral repertoire.

Anger management includes both didactic and experiential components. Educational handouts, videos, and workbooks are usually used. Ideally, participants commit to attendance for a series of weekly meetings, ranging from 4 to 10 weeks. Between the group meetings, participants are given homework assignments, such as keeping an anger diary and applying the lessons of the class in their homes and work sites. Fresh anger incidents can be brought to the class for role-plays and group discussion. Feedback from group members assists in reappraisal of situations in less hostile terms and permits practice of new anger behaviors in a supportive atmosphere. It may be useful to conduct gender-specific or culturally specific groups (Thomas, 2001).

Individuals can successfully reduce anger and foster forgiveness for an offender through religious/spiritual anger management strategies such as prayer, meditation, or yoga (Smith-MacDonald et al., 2017).

Effectiveness of anger management has been demonstrated in numerous studies, including college students, angry drivers, angry veterans, various medical and psychiatric outpatients, and parents who have difficulty controlling anger toward their children (Lee & DiGiuseppe, 2018). Family members of patients with alcohol use disorder also can benefit from anger management.

Cognitive-Behavioral Therapy for Anger

Cognitive-behavioral therapy is often recommended for the treatment of uncontrollable anger. The first step is establishing a therapeutic alliance because some angry individuals are not in a stage of readiness to change their behavior. Cognitive-behavioral therapy involves avoidance of provoking stimuli, self-monitoring regarding cues of anger arousal, stimulus control, response disruption, and guided practice of more effective anger behaviors. Relaxation or mindfulness training is often introduced early in the treatment because it strengthens the therapeutic alliance and convinces clients that they can indeed learn to calm themselves when angry. When the body relaxes, there is less physical impetus to act impulsively in a way that one will later regret (Shepherd & Cant, 2020).

AGGRESSION AND VIOLENCE

Aggression and violence command the attention of the criminal justice system as well as the mental health care system. During periods when people are a danger to others, they may be separated from the larger society and confined in prisons or locked psychiatric units. Because nurses frequently practice in these settings, management of aggressive and violent behavior is an essential skill.

Factors That Influence Aggressive and Violent Behavior

The violent individual may feel trapped, frightened, or desperate, perhaps at the end of their rope. The nurse must remember that many violent individuals have experienced childhood abandonment, physical brutality, or sexual abuse. Confinement that replicates earlier experiences of degrading treatment may provoke aggressive response, but humane care may kindle hope of recovery and rehabilitation. The response of the nurse may be critical in determining whether aggression escalates or diminishes. Aggressive or violent behavior does not occur in a vacuum. Both the patient and the context must be considered. Therefore, a multidimensional framework is essential for understanding and responding to these behaviors.

KEYCONCEPT Aggression involves overt behavior intended to hurt, belittle, take revenge, or achieve domination and control. Aggression can be verbal (sarcasm, insults, threats) or physical (property damage, slapping, hitting). Mentally healthy people stop themselves from aggression by realizing the negative consequences to themselves or their relationships.

KEYCONCEPT Impulsive aggression occurs in situations of anger and anxiety when the individual lashes out. **Instrumental aggression** is a goal-directed aggressive behavior that is premeditated and unrelated to immediate feelings of frustration or threat; it is a means to secure a goal or reward.

KEYCONCEPT Violence is extreme aggression and involves the use of strong force or weapons to inflict bodily harm to another person and in some cases to kill. Violence connotes greater intensity and destruction than aggression. All violence is aggressive, but not all aggression is violent.

Theories of Aggression and Violence

This section discusses some of the main theoretical explanations for aggression and violence. A single model or theory cannot fully explain aggression and violence; instead, choose the most useful theories for explaining a patient's experience and for planning interventions.

Biologic Theories

The brain structures most frequently associated with aggressive behavior are the limbic system and the cerebral cortex, particularly the frontal and temporal lobes. Patients with a history of damage to the cerebral cortex are more likely to exhibit increased impulsivity, decreased inhibition, and decreased judgment than are those who have not experienced such damage. The interaction of neurocognitive impairment and social history of abuse or family violence increases the risk for violent behavior, particularly for boys (Golding & Fitzgerald, 2019).

There is increasing evidence that activity of monoamine oxidase A is related to the development of impulsivity and aggression. Inhibition of this enzyme, which affects the activity of norepinephrine, serotonin, and dopamine, may play a significant role in the violence enacted by abused children, especially boys. Low serotonin levels are also associated with irritability, increased pain sensitivity, impulsiveness, and aggression (Burke et al., 2018).

Gender differences in aggressive behavior can partially be explained by neurobiology. Activation of the amygdala is correlated with higher anger scores in men but not in women. When provoked, men also have more activation in the orbitofrontal cortex, rectal gyrus, and anterior cingulate cortex than women. Activation of these areas is associated with aggression (Repple et al., 2018). Sex hormones also play a role in some aggressive behavior, with testosterone associated with aggression (Been et al., 2018). Before reading additional research evidence, try the anger exercise in [Box 20-3](#). What does daily experience suggest about biologically based aspects of the experience and expression of anger?

NCLEXNOTE In caring for a potentially aggressive patient, the nurse should recognize that biochemical

imbalance contributes to the person's inability to control aggression.

Psychological Theories

Several psychological explanations exist for aggressive and violent behaviors. This section discusses these theories and their treatment approaches.

BOX 20.3

Self-Awareness Exercise: Intensity of Anger

Imagine this scene:

You are coming home late at night. You've been at the library studying for midterm examinations and are tired. As you come up the front walk, you trip over a skateboard, probably left by one of the neighborhood children. Before you know it, you are sprawled across the front step.

What emotions threaten to overwhelm you at that moment? What contributes to the intensity of the anger that you feel?

- The pain where you scraped your leg across the cement?
- Your general state of tiredness?
- The fact that you skipped dinner?
- The five cups of coffee you had today?
- The careless children who left a toy in your way?

If the same thing had happened when you were well rested and feeling good, would the feeling and the intensity be the same?

Psychoanalytic Theories

Psychoanalytic theorists view emotions as instinctual drives. They view suppression of these drives as unhealthy and possible contributors to the development of psychosomatic or psychological disorders. Some psychoanalysts recommended the use of cathartic approaches to release patients' pent-up anger. Nurses in the mid-20th century often used interventions that directed the patient to "let it out" by pounding a pillow or ripping up telephone books. However, studies did not support the theory that catharsis reduces aggression.

Contemporary psychoanalysts do not adhere to any single explanatory model of aggression, often focusing on patients' tendencies to reenact old childhood conflicts or their defensive attempts to deny vulnerability. In working with angry patients, they focus on issues such as improved control over outbursts, heightened empathy for others, and repair of deficits in the personality structure.

During analytic therapy, patients gradually achieve greater insight into unconscious processes (Feindler & Byers, 2006; Fuchshuber & Unterrainer, 2020). Thus, they become aware of the reasons they developed maladaptive anger behaviors.

Behavioral Theories

As behavioral theories came into prominence, anger was viewed as a learned response to a stimulus rather than an instinctual drive. In the 1930s, the frustration–aggression hypothesis was advanced in which a person may experience anger and act violently in response to interference with or blocking of a goal. Laboratory experiments and the reality of everyday experience have proved the limitations of this theory (Thomas, 1990). Not all situations in which one's goal is blocked lead to anger or violence.

Social Learning Theory

In Bandura social learning theory, Bandura focuses on the role of learning and rewards in the expression of aggression and violence (Bandura, 2001). Children's observations of aggressive behaviors among family members and violence in their communities foster a context for learning that aggressive behavior is an acceptable way of getting what they want. According to this view, people develop aggressive and violent behaviors by participating in an environment that rewards aggression, such as violent video games (Teng et al., 2019).

General Aggression Model

The general aggression model is a framework that accounts for the interaction of cognition, affect, and arousal during an aggressive episode (Fig. 20-1) (Allen et al., 2018). In this model, an episode consists of *person and situation factors* in an ongoing *social interaction*. The episode is mediated through a person's thoughts, feelings, and intensity of arousal. Within this context, the individual appraises the episode and then decides about a follow-up action. The outcome is either thoughtful or impulsive action. The *person factors* include characteristics such as gender, personality traits, beliefs and attitudes, values, goals, and behavior patterns. *Situational factors* include the actual provocation (insults,

slights, verbal and physical aggression, interference with achieving goals) and cues that trigger memories of similar situations. *Cognition* includes hostile thoughts and scripts (previous behavior patterns and responses to similar episodes). Mood, emotion, and expressive motor responses (automatic reactions to specific emotions) represent the *affect component*. *Arousal* can be physiologic, psychological, or both.

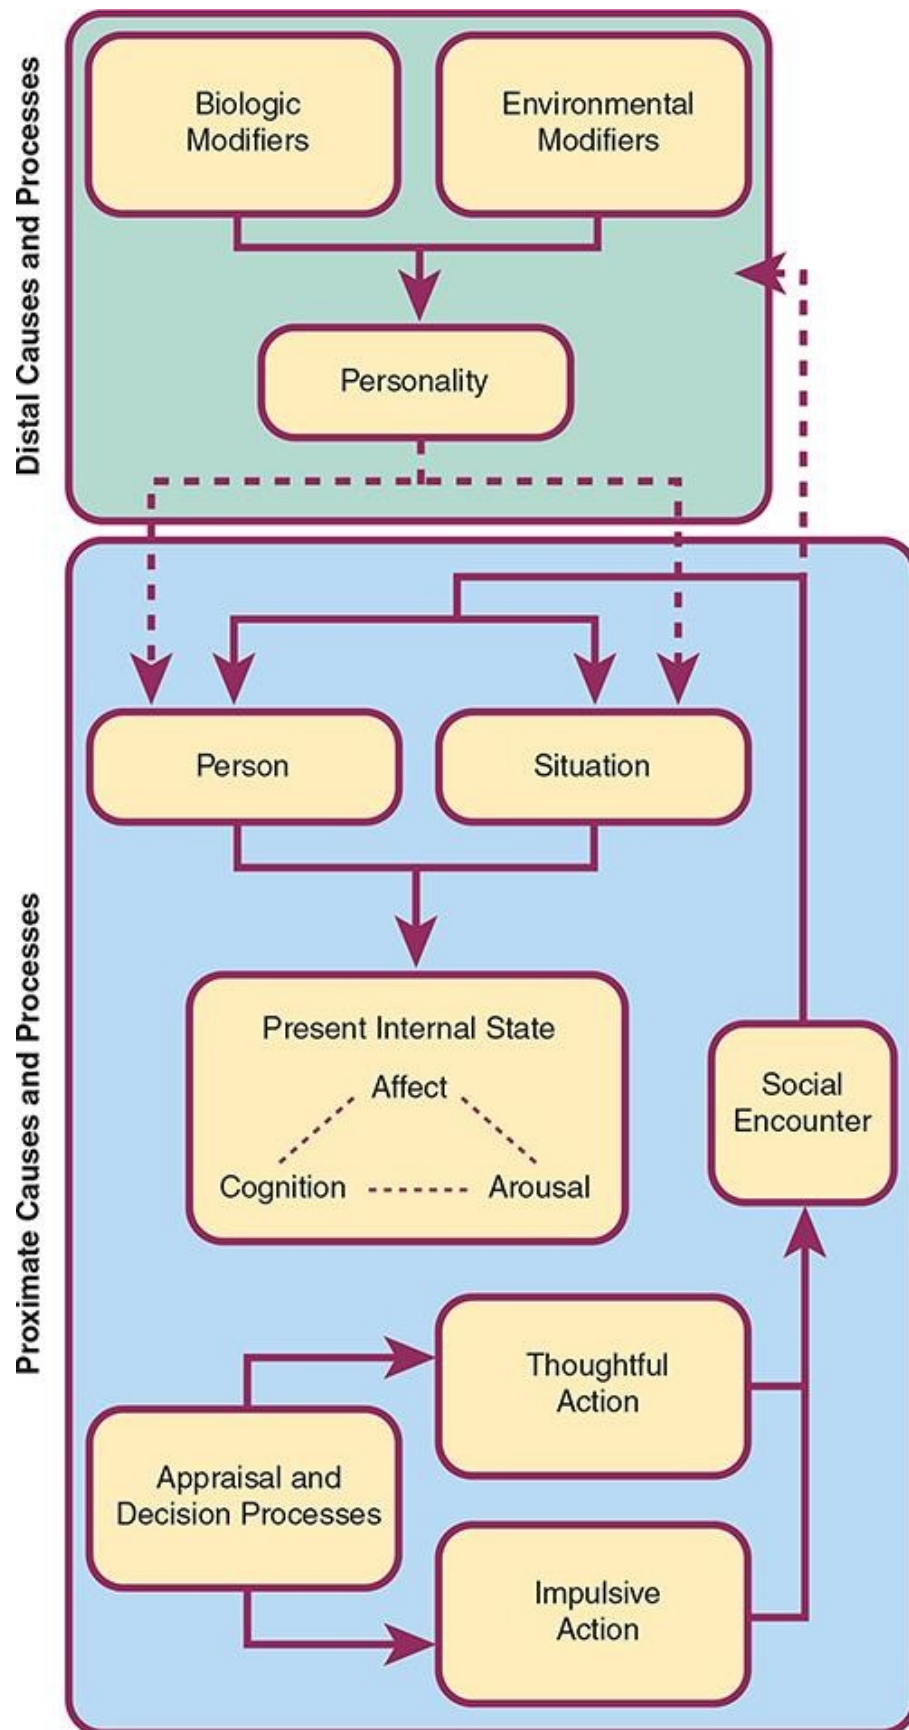

Figure 20-1: General aggression model overview. (Redrawn from Anderson, C. A., & Anderson, K. B. [2008]. Men who target women: Specificity of target, generality of aggressive behavior. *Aggressive Behavior*, 34[6], 605–622. Copyright © 2008 Wiley-Liss, Inc. PROMOTING SAFETY AND PREVENTING VIOLENCE

The paramount aims of psychiatric nurses, particularly those staffing inpatient facilities, are promoting safety and preventing violence. The nurse works toward these goals by establishing therapeutic nurse–patient relationships and creating a therapeutic milieu. Intervening with a potentially violent patient begins with assessment of the history and the predictive factors outlined in the next section.

Assessment for Aggression and Violence

The patient's history is the most important predictor of potential for aggression and violence. Schizophrenia, young age, alcohol use, drug misuse, and hostile–dominant interpersonal styles are also predictors of patient violence (d'Ettorre & Pellicani, 2017). Early life adverse circumstances, such as inadequate maternal nutrition, birth complications, traumatic brain injury, and lead exposure can contribute to risk for aggressive and criminal behaviors in adulthood (Golding & Fitzgerald, 2019). Important markers in the patient's history include previous episodes of rage and violent behavior, escalating irritability, intruding angry thoughts, and fear of losing control.

Characteristics Predictive of Aggression and Violence

The age, gender, and race of patients are *not* good predictors, but several research reports suggest that particular characteristics are predictive of violent behaviors. Usually, but not always, there are some observable precursors to

aggression and violence: staring or glaring in an intimidating manner, raising voice tone or volume, making sarcastic or demanding comments, and pacing.

Impaired Communication

Impaired communication (including hearing loss and reduced visual acuity), disorientation, and depression have been found to be consistently associated with aggressive behavior among nursing home residents with dementia (Bora et al., 2016).

In patients with cognitive impairments, the anticipation of basic needs such as thirst and hunger is important, especially when working with adults and children who cannot readily express their needs. Similarly, the nurse needs to know when the patient last voided and the pattern of bowel movements. The urge to void can be a powerful stimulus to agitated behavior. Regular toileting routines are not just interventions to prevent incontinence. Other discomforts can arise from impaired communication, such as conditions like ingrown toenails and medication side effects.

Physical Condition

The patient's physical condition contributes to the likelihood of aggression. Patients with long-standing poor dietary habits (e.g., indigent patients, patients with alcoholism) often have deficiencies of thiamine and niacin. Increased irritability, disorientation, and paranoia may result. Assessing overall dietary intake is relevant, particularly of good tryptophan sources, such as wheat, flour, corn, milk, and eggs. Intake of caffeine, a potent stimulant, should be assessed and limited as necessary.

Social Factors

The nurse should evaluate social factors, such as crisis conditions in the patient's home, family, or community that could lead to aggression or violent episodes. If assessment reveals stressful actions by family members, such as evicting the

patient from the home, attention must be devoted to mobilizing resources for family and community support and alternative housing.

Are financial or legal troubles placing increased stress on the patient? Is the patient experiencing conflict with other patients on the unit or with certain staff? People reenact in new relationships the same behaviors that created problems in old ones. Thus, behavior in a mental health facility provides important clues to a patient's habitual responses to authority figures, opposite-sex peers, and same-sex peers. Assessment data provide direction for interventions such as reassigning roommates or caregivers.

Milieu and Environmental Factors

Angry or out-of-control behavior is highly influenced by contextual factors. Successful psychiatric stabilization and treatment in a hospital often depend on the nature of the unit itself. A busy, noisy hospital unit can quickly provoke an aggressive episode. A rude comment or staff denial of a patient's request can trigger physical assault. Documented times of increased violence include meals, medication, and shift change (Salzmann-Erikson & Yifter, 2020). Crowding and density during times of high patient census are also associated with patient aggression. Inadequate staffing has been identified as a contributing factor in units with a high incidence of assault.

BOX 20.4

Characteristics of Unit Culture and Staff Behavior that Predict Patient Violence

- Rigid unit rules
- Lack of patient privacy or boundary violations
- Lack of patient autonomy (locked doors, restraints)
- Strict hierarchy of authority
- Lack of patient control over the treatment plan
- Denial of patient requests or privileges
- Lack of meaningful and predictable ward activities
- Insufficient help with activities of daily living and other needs from staff
- Patronizing behavior of staff
- Power struggles related to medications
- Failure of staff to listen, convey empathy

Hamrin, V., Iennaco, J., & Olsen, D. (2009). A review of ecological factors affecting inpatient psychiatric unit violence: Implications for relational and unit cultural improvements. *Issues in Mental Health*

Many characteristics of the unit culture and staff behavior, such as rigid rules and violation of boundaries, predict patient violence ([Box 20-4](#)). In units with a high incidence of violence, nurses should take steps to improve the milieu and staff–patient relationships. More skilled handling of “flashpoints,” such as staff denial of patient requests, can avert crisis situations.

Clinical Judgment

Safety and de-escalation of the situation are priorities when tempers flare. Preventing injury to the patient and staff are the primary goals; this is not the time to try to reason with the patient.

Interventions for Promoting Safety

Both patients and staff have a right to safety in a psychiatric unit. Nursing interventions focus on communication and development of the nurse–patient relationship, cognitive interventions, interventions for the milieu and environment, and violence prevention.

Communication and Development of the Therapeutic Nurse–Patient Relationship

Communicating with a patient who has the potential for aggression or violence follows the same principles discussed in [Chapter 10](#). Aggressive behavior can be a patient’s way to communicate a need, especially if there are communication deficits. The patient who behaves aggressively may receive rewards such as more frequent observation and more opportunities to discuss concerns with nurses.

Listening to the Patient’s Illness Experience and Concerns

Development of the therapeutic nurse–patient relationship begins with listening. Many patients with persistent mental illness have had traumatic experiences related to previous hospitalizations. Understandably, they may harbor distrust of mental health clinicians and resentment being hospitalized again. Inviting patients and families to talk about their experiences with the health care system may highlight both their concerns and resources. Simply listening to patients’ concerns and “being with” them is often as significant as “doing for” them (Box 20-5) (Thomas & Pollio, 2002).

Validating

Patients who experience intense anger and rage can feel isolated and anxious. The nurse can acknowledge these intense feelings by reflecting, “This must be scary for you.” Empathic responding can reduce emotional arousal because the patient feels understood and supported (see Chapter 10). By drawing on experience with other patients, the nurse can also reassure the patient that others have felt the same way.

BOX 20.5 • THERAPEUTIC DIALOGUE: THE POTENTIALLY AGGRESSIVE PATIENT

P.T. is a 23-year-old patient in the high observation area of an inpatient unit. The patient pacing back and forth, pounding one fist into his other hand. In the past 24 hours, P.T. has been more cooperative and less agitated. The behavior the nurse observes now is more like the behavior the patient displayed 2 days ago. Yesterday, the psychiatrist agreed to grant more freedom in the unit if the patient’s behavior improved. Even after behavior improvement, the psychiatrist refused to change the restrictions.

INEFFECTIVE APPROACH

Nurse: P.T., I can understand this is frustrating for you.

P.T.: How can you understand? Have you ever been held like a prisoner?

Nurse: I do understand, P.T. Now you must calm down or more privileges will be removed.

P.T. (voice gets louder): But I was told that calm behavior would mean more privileges. Now you are telling me calm behavior only gets me what I have got! Can’t you talk to the doctor for me?

Nurse: No, P.T., I can’t talk to the doctor. (P.T. appears more frustrated and agitated as the conversation continues.)

Effective Approach

Nurse: P.T., you look upset (observation). What happened in your conversation with the psychiatrist? (seeking information)

P.T.: Yesterday, the doctor said calmer behavior would mean more freedom in the unit. I have tried to be calmer and not to swear. You said you noticed the difference. But today the doctor says “no” to more freedom.

Nurse: Some people might feel cheated if this happened to them (validation). Is that how you feel?

P.T.: Yeah, I feel real cheated. Nothing I do makes a difference. That’s the way it is here, and that’s the way it is when I am out of the hospital.

Nurse: Sounds like experiences like this leave you feeling powerless (validation).

P.T.: I don’t have any power, anywhere. Sometimes when I have no power, I get mean. At least then people pay attention to me.

Nurse: In this situation with your doctor, what would help you feel that you had some power? (Inviting patient partnership)

P.T.: Well, if the doctor would listen to me or read my chart.

Nurse: I am a bit confused by the psychiatrist’s decision. I won’t make promises that your privileges will change, but would it be okay with you if I talk with the doctor?

P.T.: That would make me feel like someone is on my side.

CRITICAL THINKING CHALLENGE

- In the first scenario, how did the nurse escalate the situation?
- Compare the first scenario with the second. How are they different?

Providing Choices

When possible, the nurse should provide the patient with choices, particularly patients who have little control over their situation because of their condition. Offering concrete choices is better than offering open-ended options. For example, a patient who is experiencing a manic episode and is confined to their room may have few options in their daily schedule. However, they may be allowed to make choices about food, personal hygiene, and which pajamas to wear.

Cognitive Interventions to Address Aggression

Cognitive interventions are very useful in interacting with a potentially aggressive patient (see [Chapter 13](#)). These interventions are useful when the patient is in a nonaggressive state and willing to discuss the irrational thought process underlying aggressive episodes. These periods of interaction allow exploration of the patient's beliefs and provision of reassurance, support, and education.

NCLEXNOTE The best time to teach the patient techniques for managing anger and aggression is when the patient is not experiencing the provoking event. Cognitive therapy approaches are useful and can be prioritized according to responses.

Providing Patient Education

Inpatient hospitalization offers opportunities for education of patients and families about a variety of topics. Nurses can seize “teachable moments” to convey important principles of anger management. For example, after an outburst of loud cursing by J., who mistakenly thought another patient, S., had stolen their cigarettes, the nurse helped them consider what they could have done differently in the situation. J. was more amenable to learning about calming techniques and problem-solving strategies at this time because their behavior had resulted in adverse consequences (estrangement from S., disruption of the dayroom during a popular bingo game, and cancellation of S.'s weekend pass). This incident could also be used for teaching in a subsequent group meeting of inpatients. Many units have daily meetings that permit processing of such conflicts. S. could be invited to express feelings about being falsely accused of stealing. Other patients may reveal how distressed they were when J. was cursing loudly, providing their useful peer feedback about J.'s outburst. Together, group members could generate ideas for more appropriate behavior.

Developing Prevention Strategies

Although patients are not always aware of it, escalation of feelings, thoughts, and behavior from calmness to violence may follow a pattern. Disruption of the pattern can sometimes be a useful means for preventing escalation and helping the patient regain composure. Patients can learn to identify their own personal warning signs of aggression and develop aggression-prevention strategies. Both inpatients and outpatients have benefited from nurse-led group therapy for

aggressive behaviors. Group members recognized their underlying feelings of helplessness and loss of control and successfully decreased their aggressive behaviors (Lanza, 2018). Nurses can suggest a variety of strategies to interrupt patterns:

- Counting to 10
- Using a relaxation or breathing technique (see [Chapter 11](#))
- Removing oneself from interactions or stimuli that may contribute to increased distress (voluntarily taking a “cooling-off walk” or “time-out”)
- Doing something different (e.g., reading, listening to quiet music, watching television)

Milieu and Environmental Interventions

The inpatient environment can be modified proactively to decrease the potential of aggressive and violent behaviors ([Box 20-6](#)).

Reducing Stimulation

For people whose perceptions or thoughts are disordered from brain damage, degeneration, or other thought-processing difficulties, modification of the environment may be one of the main interventions. The patient with a brain injury, progressive dementia, or distorted vision may be experiencing intense and highly confusing stimulation even though the environment, from the nurse’s or family’s perspective, seems calm and orderly.

Likewise, introducing more structure into a chaotic environment can help decrease the risk for aggressive behavior. It is possible to make stimuli meaningful or to simplify and interpret the environment in many practical ways, such as by identifying people or equipment that may be unfamiliar, providing cues as to what is expected (e.g., posting signs with directions, putting a toothbrush and toothpaste by the sink), and removing or silencing unnecessary stimuli (e.g., turning off paging systems).

BOX 20.6

Environmental Management: Maintaining Patient Safety

Definition

Maintaining patient safety includes identifying and eliminating environmental risks for persons who are at risk of injuring self or others.

Activities

- Search the environment routinely to maintain it as hazard free.
- Remove potential weapons (e.g., sharps, ropelike objects) from the environment.
- Search the patient and belongings for weapons or potential weapons
- Monitor the safety of items that visitors bring to the environment.
- Instruct visitors and other caregivers about relevant patient safety issues.
- Limit patient use of potential weapons (e.g., sharps, ropelike objects).
- Monitor patient during use of potential weapons (e.g., razors).
- Place the patient with potential for self-harm with a roommate to decrease isolation and opportunity to act on self-harm thoughts, as appropriate.
- Assign a single room to the patient with potential for violence toward others.
- Place the patient in a bedroom located near a nursing station.
- Limit access to windows unless they are locked and shatterproof, as appropriate.
- Lock utility and storage rooms.
- Provide paper dishes and plastic utensils at meals.
- Place the patient in the least restrictive environment that still allows for the necessary level of observation.
- Provide ongoing surveillance of all patient access areas to maintain patient safety and therapeutically intervene, as needed.
- Remove other individuals from the vicinity of a violent or potentially violent patient.
- Maintain a designated safe area (e.g., seclusion room) for patient to be placed when violent.
- Provide plastic, rather than metal, clothes hangers, as appropriate.

Adapted from the Mental Health Environment of Care Checklist. VHA National Center for Patient Safety, Department of Veterans Affairs. Version 06–01–2015.

<http://www.patientsafety.va.gov/professionals/onthejob/mentalhealth.asp>

Considering the environment from the patient's viewpoint is essential. For instance, if the surroundings are unfamiliar, the patient will need to process more information. Lack of a recognizable pattern or structure further taxes the patient's capacity to encode information. Appropriate interventions include clarifying the meaning and purpose of people and objects in the environment, enhancing the patient's sense of control and the predictability of the environment, and reducing other stimuli as much as possible.

Interventions for Managing Imminent Aggression and Violence

De-Escalation

Authentic engagement with the patient is the core component in a therapeutic de-escalation by the nurse. Creative, patient-centered strategies, not techniques of physical restraint, are of paramount importance. Individualizing interventions is important. In some patients, loudness and pacing can be ignored; in others, these behaviors indicate an escalation of agitation.

De-escalating potential aggression is always preferable to challenging or provoking a patient. De-escalating (commonly known as “talking the person down”) is a skill that every nurse can develop. Trying to clarify what has upset the patient is important although not all patients are capable of articulating what provoked them, as in cases where violent acting out has been triggered by delusions or hallucinations (Moylan, 2015). Some analyses will have to take place after a crisis has been diffused. The nurse can use therapeutic communication techniques to prevent a crisis or diffuse a critical situation (see [Box 20-5](#)).

The nurse who works with potentially aggressive patients should do so with respect and concern. The goal is to work with patients to find solutions, approaching these patients calmly and empathizing with the patient’s perspective. Offering a simple apology to an agitated patient can circumvent a power struggle (Berring et al., 2016). In dealing with aggression, as in other aspects of nursing practice, at times the best intervention is silence. It is easy to equate intervention with activity, the sense that “I must do something.” But offering quiet calmness may be enough to help a patient regain control of their behavior.

KEYCONCEPT **Intervention fit** The nurse who intervenes from within the context of the therapeutic relationship must be cognizant of the fit of a particular intervention.

Interventions that are appropriate in early phases of escalation differ from those used when the patient’s agitation is greater. The patient’s affective, behavioral, and cognitive response to an intervention provides information about its effects and guides the nurse’s next response. The following approaches are important in caring for patients who are aggressive or violent:

- Using nonthreatening body language
- Respecting the patient’s personal space and boundaries
- Having immediate access to the door of the room in case you need to leave the room
- Choosing to leave the door open to an office while talking to a patient

- Knowing where colleagues are and making sure those colleagues know where you are
- Removing or not wearing clothing or accessories that could be used to harm you, such as scarves, necklaces, or dangling earrings

Administering and Monitoring PRN Medications

Patients with potential for aggression and violence usually have a PRN (as-needed) medication order for agitation and aggression. Administering a PRN medication is left to the discretion of the nurse, who makes a judgment about the patient after careful assessment. Patients often recognize when a PRN medication is needed.

Avoiding the Use of Seclusion and Restraint

Seclusion and restraint have been used by nurses when patients need to be separated from other patients on the unit. The decision to use seclusion and restraint is a dynamic process involving evaluation of the risks to all who are present, as well as the need to maintain a therapeutic milieu. The decision is usually an interdisciplinary decision that follows ethical and legal standards as well as accrediting guidelines (Moylan, 2015).

The use of seclusion and restraint is now recognized as a traumatic experience for patients. Most patients with a mental disorder have already experienced traumas, usually in childhood. The act of placing an individual in seclusion or restraints retraumatizes the individual (Chieze et al., 2019). Therefore, the trauma-informed care movement has influenced organizational policy making (Moylan, 2015). Many hospitals no longer use restraints as a form of behavioral management. In instances where seclusion and restraint are used, they should be the last resort to protect the patient or the staff. De-escalation interventions should be tried first and clearly documented in the patient's record.

American institutions that receive Medicare or Medicaid reimbursement must adhere to guidelines issued by the Center for Medicare and Medicaid Services. These guidelines specify that a registered nurse must verify the need for restraint or seclusion and then contact the physician or other licensed practitioner; within 1 hour, that practitioner must examine the patient. Individual states have also enacted laws to regulate the use of restraints, and professional organizations released position statements on restraints as the last resort in an emergency

(American Psychiatric Nurses Association, 2014).

Restraint-related injuries and deaths have prompted many facilities to ban their use entirely and train staff in alternative techniques. Comfort or sensory rooms are becoming more widespread, providing an appealing alternative to coercive interventions by unit staff. These rooms can provide stimulation for sight, smell, hearing, touch, and taste in a demand-free environment that is controlled by the patient. The rooms may reduce patients' distress and agitation and reduce the need for seclusion and restraint (Björkdahl et al., 2016). Some treatment facilities offer items such as weighted blankets, massage creams, and "squishy" balls to augment other de-escalation measures (Blackburn et al., 2016).

Evaluation and Treatment Outcomes

Treatment outcomes can be considered at both individual and aggregate levels. The desired outcome at the individual level is for the patient to regain or maintain control over aggressive or potentially aggressive thoughts, feelings, and actions. The nurse may observe that the patient shows decreased psychomotor activity (e.g., less pacing), has a more relaxed posture, speaks more directly about feelings of anger and personal needs, requires less sedating medication, shows increased tolerance for frustration and the ability to consider alternatives, and makes effective use of other coping strategies.

If restraints or seclusion have been used, a debriefing occurs with the persons involved in the incident, including the patient. This approach allows for a collaborative, community approach to preventing patient violence and avoids blaming one assailant for incidents provoked by a variety of contextual and interpersonal factors. The practice of prompt debriefing and reflection can ultimately transform a treatment setting to a learning community (Berring et al., 2016).

Evidence of a reduction in risk factors in the treatment setting include decreased noise and confusion in the immediate environment; calmness on the part of nursing staff and others; and a climate of safety, clear expectations, and mutual acceptance and respect. In units, day hospitals, or group home settings, indicators of positive treatment outcomes include a reduction in the number and severity of assaults on staff and other patients, fewer incident reports, and increased staff competency in de-escalating potentially violent situations.

For practice improvement and research purposes, the American Psychiatric Nurses Association Council for Safe Environments recommends measuring violence at a standard rate of incidents per 1,000 days of patient care, using validated tools such as the Overt Aggression Scale and the Modified Version of the Overt Aggression Scale. These tools can be incorporated into nursing assessments and documented in electronic health records. The resultant data can be used to evaluate effectiveness of interventions and adequacy of staffing (Allen et al., 2019).

Responding to Assault on Nurses

Because nurses have extended contact with patients during highly stressful circumstances, there is always the risk that they may be the recipients of patient aggression. Psychiatric nurses are assaulted more often than medical–surgical nurses, but physical violence and mental abuse occur more often in the emergency room than in the mental health unit (Pekurinen et al., 2017).

Assaults on nurses by patients can have both immediate and long-term consequences (see [Table 20-3](#)). Reported assaults range from verbal abuse or threats and minor altercations to severe injuries, rape, and murder. Any assault can produce severe consequences for the victim including posttraumatic stress disorder. After a violent incident, the nurse may avoid the patient or watch for any signs of patient remorse; the nurse’s response differs depending on the nurse’s feelings of safety and comfort with the patient. The nurse’s interpretation of the assaultive behavior will depend on many factors such as experience with assault, the type of assault (impulsive or instrumental), and the nurse’s injury.

Table 20-3: Nurses’ Responses to Assault

Response Type	Personal	Professional
Affective	<ul style="list-style-type: none">• Irritability• Depression• Anger• Anxiety• Apathy	<ul style="list-style-type: none">• Erosion of feelings of competence, leading to increased anxiety and fear• Feelings of guilt or self-blame• Fear of potentially violent patients

Cognitive	<ul style="list-style-type: none"> • Suppressed intrusive thoughts of assault 	<ul style="list-style-type: none"> • Reduced confidence in judgment • Consideration of job change
Behavioral	<ul style="list-style-type: none"> • Social withdrawal 	<ul style="list-style-type: none"> • Possible hesitation in responding to other violent situations • Possible overcontrolling • Possible hesitation to report future assaults • Possible withdrawal from colleagues • Questioning of capabilities by coworkers
Physiologic	<ul style="list-style-type: none"> • Disturbed sleep • Headaches • Stomach aches • Tension 	<ul style="list-style-type: none"> • Increased absenteeism because of somatic complaints

Unfortunately, patient aggression directed toward nurses is often downplayed or tolerated by nurses as “part of the job.” Nurses seldom report attacks to the police or prosecute their attackers, but such incidents should be reported to supervisors and possibly to legal authorities, depending on the circumstances. Aggression by patients must be addressed vigorously because it can threaten the other patients, other health care professionals, family members, and visitors, as well as the nursing staff. Reporting violent attacks increases public awareness and increases the likelihood that protective legislation will be enacted. The environment should be modified with the addition of security alarms, video monitors, and de-escalation teams.

All nurses must be provided with training programs in the prevention and management of aggressive behavior. These programs, similar to courses on cardiopulmonary resuscitation, impart both knowledge and skills, lessening the likelihood of emotional freezing in the presence of violent patient behavior. Similar to cardiopulmonary resuscitation training, the courses should be provided to undergraduate students and regularly offered to practicing nurses, so that they have opportunities to reinforce and update what they have learned (Searby et al., 2019). Some states have enacted legislation mandating workplace

violence prevention programs, but the curricula vary, and the quality of training lacks systematic evaluation. Commercially marketed training programs have been criticized because they fail to consider the predatory aspect of some patients' violence and fail to cite nursing research.

RESEARCH AND POLICY INITIATIVES

Additional understanding of the phenomena of anger, aggression, and violence as they occur in the clinical setting is needed. Nurses must research the effectiveness of particular anger and aggression management interventions. Although much of this chapter focused on individuals who need to *downregulate* anger, the reader must remember that anger suppressors have a need to *upregulate* their anger and express it more assertively. Learning to express legitimate angry feelings was a significant step in the trajectory of recovery for women who had survived childhood abuse (Thomas et al., 2012). Treatments should be tailored based on assessment data and patients' progress.

There is a moral imperative for nurses to be involved in combating violence in the larger community. Lessening anger and violence in the workplace and the home demands involvement of all mental health professionals. Nurses can share their expertise with parents, children, teachers, and community agencies. Nurses are well positioned to teach health-promoting anger management classes in diverse practice settings, such as outpatient clinics, schools, and corporate sites. Classes for children and adolescents can be of great benefit because young people are forming the anger habits that will continue into adulthood. Youth who have high levels of anger are at risk for misuse of alcohol and other substances (Serafini et al., 2016) as well as interpersonal conflicts that hamper their educational and occupational success.

SUMMARY OF KEY POINTS

- Anger is an emotional state, usually temporary, that can be expressed constructively or destructively. Destructive anger alienates other people and invites retaliation.

- Anger, aggression, and violence should not be viewed as a continuum. The anger of ordinary people seldom progresses to aggression or violence. Anger does not necessarily lead to aggression or violence.
- Anger management is a useful psychoeducational intervention that is effective with a wide variety of nonviolent individuals. However, anger management is not designed to modify violent behavior.
- Several theories explain anger, aggression, and violence and include neurobiological and psychosocial theories. These theories serve as the basis of assessment and interventions.
- The general aggression model accounts for the interaction of cognition, affect, and arousal during an aggressive episode.
- There is no one factor that predicts aggression or violence. Factors that have been observed to be precursors are staring and eye contact, tone and volume of voice, anxiety, and pacing.
- Nursing interventions can be affective, cognitive, behavioral, or sociocultural. A therapeutic milieu supports a nonviolent culture.
- Nurses who experience assault may experience changes in affective, cognitive, behavioral, and physiological areas.
- Seclusion or restraints should be used only as a last resort.
- Patient aggression and violence are serious concerns for nurses in all areas of clinical practice. Training in policies and procedures for the prevention and management of aggressive episodes should be available in nursing education programs and all work settings.

CRITICAL THINKING CHALLENGES

1. M.J., a 24-year-old, has just been admitted to an inpatient psychiatry unit transferring from the emergency department after being treated for a drug overdose. Patient is sullen when introduced to the roommate and refuses to answer the admission assessment questions. The nurse tells the patient that they will come back in 30 minutes to complete the assessment. A few minutes

later, the patient approaches the nursing station and asks in a demanding tone to talk with someone because of being completely ignored.

- a. What frameworks can the nurse use to understand M.J. behavior?
 - b. At this point in time, what data are available to develop a plan of care?
 - c. What interventions might the nurse choose to use to help M.J. behave in a manner that is consistent with the norms of this inpatient unit?
2. Discuss the influence of gender and cultural norms on the expression of anger. When a nurse is caring for a patient from a culture that the nurse is not familiar with, what could the nurse ask to ensure that their expectations of the patient's behavior are consistent with the gender and cultural norms of the patient?
3. Under what circumstances should people who are aggressive or violent be held accountable for their behavior? Are there any exceptions?
4. When a nurse minimizes verbally abusive behavior by a patient, family member, or health care colleague, what implicit message does they send?

Movie Viewing Guides

Mandela: Long Walk to Freedom: 2013. South African icon Nelson Mandela displays the gamut of angry behaviors in this biographic epic: (1) righteous anger on behalf of his clients when he was a young lawyer; (2) fiery anger at the cruel persecution of Blacks during apartheid; and (3) violence against the government after the failure of nonviolent protests to achieve freedom from oppression. Bomb throwing at government buildings results in 27 years of imprisonment, which could have created lasting bitterness against his oppressors. Yet after his release, Mandela forgives those who had imprisoned him, becomes the first Black president of his country, and receives the Nobel Peace Prize. This remarkable true story provides many lessons for all.

VIEWING POINTS: Although most of us will never be forced to endure such intolerable conditions, we all experience times of unfair or unkind treatment. How can we learn to use our anger productively or learn to let it go by forgiving those who wronged us?

Crisis, Loss, Grief, Bereavement, and Disaster Management

Mary Ann Boyd

KEYCONCEPTS

- Bereavement
- Crisis
- Disaster
- Grief

- Loss

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Describe the types of crises and their impact on mental health.
2. Discuss theoretical models explaining grief, uncomplicated bereavement, and complicated bereavement.
3. Discuss the impact of disasters on mental health.
4. Discuss nursing care for persons experiencing crises, loss, grief, bereavement, and disaster.
5. Evaluate the effects of crises, losses, and disasters on lifestyle and survival.
6. Explain the psychological impact of crises, losses, and disasters on survivors of catastrophic events.

KEY TERMS

- ABCs of psychological first aid
- Acute grief
- Complicated bereavement
- Debriefing
- Developmental crisis
- Dual process model
- Loss-oriented coping
- Maturation crises
- Oscillation
- Predeath grief
- Restoration-oriented coping
- Situational crisis
- Traumatic crisis
- Uncomplicated bereavement

INTRODUCTION

Successfully surviving crises, loss, and disaster may make a difference between being mentally healthy or mentally ill. This chapter explores the concepts of

crisis, loss, grief, bereavement, and disaster management; broadens the scope and understanding of the responses of persons to crisis, loss, and disaster situations; and describes how the nursing process can be used to care for persons experiencing these events.

CRISIS

Adaptation and coping are a natural part of life (see Chapter 19). Crisis occurs when there is a perceived challenge or threat that overwhelms the capacity of the individual to cope effectively with the event at any age. Life is disrupted, and unexpected emotional (e.g., sadness, depression, anxiety) and biologic (e.g., nausea, vomiting, diarrhea, headaches) responses occur (see [Box 21-1](#)). Functioning can be severely impaired.

BOX 21.1

Grief

Physical: stunned, weight gain/loss, insomnia, anorexia, exhausted, restless, aching arms, sleep difficulties, headaches, aching arms, feels ill, palpitations, breathlessness, sighing, lack of strength, blurred vision¹

Emotional: crying, sobbing, sadness, guilt, anger, sense of failure, irritability, resentment, bitterness, denial, frustration, shame, fear of own death, oversensitivity to environment, senses the presence of the deceased

Social: social withdrawal from normal activity, isolation from others

Cognitive: forgetful, difficulty in making decisions, disorganized, concentration is difficult, preoccupation with thoughts of the deceased, time confusion, short attention span, think they are going crazy

KEYCONCEPT **Crisis** is a time-limited event that triggers adaptive or nonadaptive responses to maturational, situational, or traumatic experiences. A crisis results from stressful events for which previous coping mechanisms fail to provide adequate adaptive skills to address the perceived challenge or threat. Adaptation to crisis typically occurs in 6 weeks.

A crisis occurs when an individual is at a breaking point. A crisis can have either positive or negative outcomes. If positive, there is an opportunity for growth and change as new ways of coping are learned. If negative, suicide, homelessness, or depression can result. A crisis generally lasts no more than 4 to

6 weeks. At the end of that time, the person in crisis should have begun to come to grip with the event and begun to harness resources to cope with its long-term consequences. By definition, there is no such thing as a chronic crisis. People who live in constant turmoil are not in crisis but in chaos.

Many events evoke a crisis, such as natural disasters (e.g., floods, tornadoes, earthquakes) and human-made disasters (e.g., wars, bombings, airplane crashes) as well as traumatic experiences (e.g., rape, sexual abuse, assault). In addition, interpersonal events (marriage, birth of a child) create crises in the lives of any person.

Feelings of fear, desperation, and being out of control are common during a crisis, but the precipitating event and circumstances are unusual or rare, perceived as a threat, and specific to the individual. For example, a disagreement with a family member may escalate into a crisis for one person, but not another. If the person is significantly distressed or social functioning is impaired, a diagnosis of acute stress disorder should be considered (American Psychiatric Association [APA], 2013). The person with an acute stress disorder has dissociative symptoms and persistently reexperiences the event (See Chapter 29).

Historical Perspectives of Crisis

The psychiatrist Caplan (1961) defined a crisis as occurring when a person faces a problem that cannot be solved by customary problem-solving methods. When the usual problem-solving methods no longer work, a person's life balance or equilibrium is upset. During the period of disequilibrium, there is a rise in inner tension and anxiety followed by emotional upset and an inability to function. This conceptualization of phases of a crisis is used today (Fig. 21-1). According to Caplan, during a crisis, a person is open to learning new ways of coping to survive. The outcome of a crisis is governed by the kind of interaction that occurs between the person and available key social support systems.

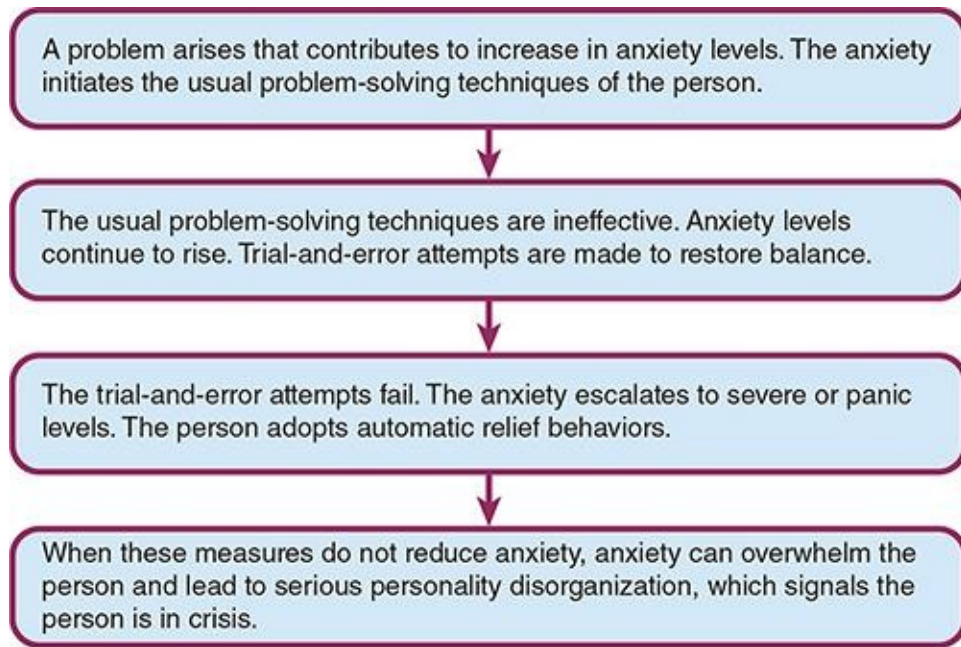

FIGURE 21-1: Phases of crisis.

Types of Crises

Research has focused on categorizing types of crisis events, understanding responses to a crisis, and developing intervention models that support people through a crisis.

Developmental Crisis

While Caplan was creating his crisis model, Erik Erikson was formulating ideas about crisis and development. He proposed that **developmental crisis** continues to be used today to describe significant maturational events, such as leaving home for the first time, completing school, and accepting the responsibility of adulthood.

Situational Crisis

A **situational crisis** occurs whenever a specific stressful event threatens a person's physical and psychosocial integrity and results in some degree of psychological disequilibrium. The event can be an internal one, such as a disease process, or any number of external threats. A move to another city, a job promotion, or graduation from high school can initiate a crisis even though they are positive events. Graduation from high school marks the end of an established routine of going to school, participating in school activities, and doing homework assignments. When starting a new job after graduation, the former student must learn an entirely different routine and acquire new knowledge and skills. If a person enters a new situation without adequate coping skills, a crisis may occur.

Traumatic Crisis

A **traumatic crisis** is initiated by unexpected, unusual events that can affect an individual or a multitude of people. In such situations, people face overwhelmingly hazardous events that entail injury, trauma, destruction, or sacrifice. Examples of events include national disasters (e.g., racial persecutions, riots, war), violent crimes (e.g., rape, murder, kidnappings, and assault and battery), and environmental disasters (e.g., earthquakes, floods, forest fires, hurricanes).

Teamwork and Collaboration: Working Toward Recovery

The goal for people experiencing a crisis is to return to the precrisis level of functioning. The role of the nurse is to provide a framework of support systems that guide the patient through the crisis and facilitate the development and use of positive coping skills.

Box 21.2

Decision Tree for Determining Referral

Situation: A 35-year-old woman is being seen in a clinic because of minor burns she received during a

house fire. Her home was completely destroyed. She is tearful and withdrawn, and she complains of a great deal of pain from her minor burns. Biopsychosocial assessment is completed.

Assessment Result

Nursing Action

Patient has psychological distress but believes that her social support is adequate. She would like to talk to a nurse when she returns for her follow-up visit.

Provide counseling and support for the patient during her visit. Make an appointment for her return visit to the clinic for follow-up.

The patient is severely distressed. She has no social support. She does not know how she will survive.

Refer the patient to a mental health specialist. The patient will need crisis intervention strategies provided by a mental health specialist.

EMERGENCY CARE ALERT! It is important to be acutely aware that a person in crisis may be at high risk for suicide or homicide. To determine the level of effectiveness of coping capabilities of the person, the nurse should complete a careful assessment for suicidal or homicidal risk. If a person is at high risk for either, the nurse should consider referral for admission to the hospital.

NCLEXNOTE During a crisis, the behaviors and verbalizations of a person may provide data that are indicative of a mental illness. Nursing care should be prioritized according to the severity of responses. After the crisis has been resolved, assess whether the abnormal thoughts or feelings disappear.

During an environmental crisis (e.g., flood, hurricane, forest fire) that affects the well-being of many people, nursing interventions will be a part of the community's efforts to respond to the event. This is covered in more detail in the section of the chapter on disasters. On the other hand, when a personal crisis occurs, the person in crisis may have only the nurse to respond to their needs. After the assessment, the nurse must decide whether to provide the care needed or to refer the person to a mental health specialist. [Box 21-2](#) offers guidance in making this decision.

EVIDENCE-BASED NURSING CARE OF PERSON IN CRISIS

Mental Health Nursing Assessment

Because the response to a crisis is individual and differs from person to person, the nurse should make sure that a very complete assessment is done. The first priority is determining the extent of physical injury or trauma. The person should receive medical care for any injuries. Once medically stable, changes in health practices following the crisis provide clues to the severity of the disruption in functioning.

Physical Health

Maintaining health is important because a crisis can be physically exhausting. Disturbances in sleep and eating patterns and the reappearance of physical or psychiatric symptoms are common. Changes in body function may include tachycardia, tachypnea, profuse perspiration, nausea, vomiting, dilated pupils, and extreme shakiness. Some individuals may exhibit loss of control and have total disregard for their personal safety. If sleep patterns are disturbed or nutrition is inadequate, the individual may not have the physical resources to deal with the crisis.

Emotional and Behavioral Responses

The mental health nursing assessment focuses on the individual's emotions and coping strengths. In the beginning of the crisis, the person may report feelings of numbness and shock. Responses to psychological distress should be differentiated from symptoms of psychiatric illnesses that may be present. Later, as the reality of the crisis sinks in, the person will be able to recognize and describe the felt emotions. The nurse should expect these emotions to be intense and be sure to provide some support during their expression.

Initially, the individual's thoughts and behaviors may be erratic and illogic. The nurse should assess for evidence of depression, confusion, uncontrolled weeping or screaming, disorientation, or aggression. The person may be suffering from a loss of feelings of well-being and safety. In addition, panic responses, anxiety, and fear may be present. The ability to cope by problem-

solving may be disrupted. By assessing the person's ability to solve problems, the nurse can evaluate whether they can cognitively cope with the crisis situation and determine the kind and amount of support needed.

Coping Skills

Coping skills should be identified in an assessment of anyone undergoing a crisis. The coping skills of some individuals are sufficient to weather a crisis, but many skills are inadequate for the situation. Unusual behaviors may emerge that are ineffective. There may be evidence of self-mutilation activities or suicide ideation.

Social Functioning and Support

It is critical to assess the person's perception of the problem and the availability of support systems (emotional and financial). The extent of disruption of normal daily activities and routines is assessed to determine the need for additional support. The person may not be shopping, paying bills, or cleaning the house. The nurse should identify the social network of family and friends who are available to provide help and support.

Clinical Judgment

Safety is a priority. Physical consequences of the crisis are the first priority. There may be tachycardia or hyperventilation. Reports of potential self-physical harm such as suicide ideation or intention should be the focus of the next intervention. Body systems can change during a crisis. Diarrhea and urinary incontinence can occur. Food and shelter needs should be considered. The emotional and psychological consequences of the crisis such as fear, extreme distress will also be important to address.

THERAPEUTIC RELATIONSHIP

A nurse is often meeting the person in crisis for the first time and will need to skillfully apply therapeutic communication techniques to meet the individual's immediate mental health needs. Patience, listening, and empathy are important tools that along with a calm, nurturing approach can help establish trust. In some instances, the nurse has a relationship with the patient who reaches out during a crisis. In that instance, the nurse will have already established the therapeutic relationship and can quickly provide meaningful support and interventions. Be careful not to give unrealistic or false reassurances of positive outcomes over which you have no control. For example, it is not a good idea to reassure the person that everything will be alright because things may get worse, not better.

NCLEXNOTE Individual responses to a crisis can be best understood by assessing the usual responses of the person to stressful events. The response to the crisis will also depend on the meaning of the event to the person. The use of therapeutic communication principles is a priority when caring for a person who has experienced a crisis or disaster.

MENTAL HEALTH NURSING INTERVENTIONS

Immediate goals during a crisis may be providing first aid, preventing the person from committing suicide or homicide, arranging for food and shelter (if needed), and mobilizing social support. After safety needs are met, the individual can work toward recovery by addressing other goals such as reestablishing self-care routines and using positive coping strategies. Strengths identified in the assessment supporting a healthy lifestyle prior to the crisis should be used to develop a plan of care.

The person may have exercised regularly and is ready to use exercise as a way of dealing with the stress. Or the person may have had a healthy diet before the crisis and is now ready to reengage in healthier eating choices. Guidelines for crisis intervention and examples are presented in [Table 21-1](#). Individuals should be encouraged to report any depression, anxiety, or interpersonal difficulties during the recovery period.

Table 21-1: Guidelines for Crisis Intervention

Approach	Rationale	Example
----------	-----------	---------

Support the expression (or nonexpression) of feelings according to cultural or ethnic practices.	Emotional support helps the person face reality. The emotional expression by the victim may be culturally driven.	Ask the person to actualize the loss using active and reflective listening. "Where you there when they died?" "Tell me how they died?" "What special remembrances do you have?" If the person is crying, sobbing, or angry; allow for the expression of their emotions. Sit quietly beside. When they are done you can say, "I can tell how terribly sad or angry you are." Try to avoid handing a tissue. Wait for them to look for a tissue before you hand them one.
Help the person think clearly and focus on one implication at a time.	Focusing on all the implications at once can be too overwhelming.	An individual left a partner because of abuse. At first, focus only on living arrangements and safety. "You can say, there are several things we need to focus on now for your safety." At another time, discuss the other implications of the separation.
Avoid giving false reassurances, such as "It will be all right;" "It is for the best."	Giving false reassurances blocks communication. It may not be all right.	Patient: "My doctor told me that I have a terminal illness." Nurse: Restatement: "Your doctor told you that you have a terminal illness. What does that mean to you?"
Clarify fantasies with facts.	Accurate information is needed to solve problems.	A young mother is holding her child who has died. The mother expresses disbelief this has happened. Quietly sit beside her. The longer she holds her child, the realization this has occurred will settle within her. You do not need to point out the obvious.
Link the person and family with community resources, as needed.	Social support can ease the effect of the crisis or loss.	Provide information about a meeting of a support group such as that of the American Cancer Society, Alzheimer Support Groups; Compassionate Friends; resolve through sharing or other local bereavement support groups.

Adapted from Lazarus, R. (1991). *Emotion and adaptation* (p. 122). Oxford University Press; Worden, W. (1991). *Grief counseling and grief therapy: A handbook for the mental health practitioner*. Springer.

Self-Care

A person needs to eat and sleep in order to have the energy to cope with a crisis. Personal hygiene may be suffering. The nurse should encourage the person to reestablish a healthy diet, practice sleep hygiene strategies, and attend to personal grooming. If the person is unable to function, a referral can be made to other health care clinicians. Medication may be needed to help maintain a high level of psychophysical functioning.

Medication Interventions

Medication cannot resolve a crisis, but the judicious use of these agents can help reduce its emotional intensity. For example, the use of an antianxiety medication such as lorazepam may help the person through the initial shock of the crisis (see [Box 21-3](#)).

Counseling

Counseling reinforces healthy coping behaviors and interaction patterns. Counseling, which focuses on identifying emotions and positive coping strategies, helps the person integrate the effects of the crisis into a real life experience. Responses to crisis differ with individuals. Some may present with behaviors that indicate transient disruptions in their ability to cope. Others may be totally devastated. At times, virtual counseling may provide the person with enough help that face-to-face counseling is not necessary. If counseling strategies do not work, other stress reduction and coping enhancement interventions can be used (see [Chapter 19](#)). The nurse should refer anyone who cannot cope with a crisis to a mental health specialist for an evaluation.

Social Support Strategies

A crisis often disrupts a person's social network, leading to changes in available social support. Development of a new social support network may help the person cope more effectively with the crisis. Supporting the development of new

support contacts within the context of available social networks can be done by contacting available local and state agencies for assistance as well as specific private support groups and religious groups.

BOX 21.3

Lorazepam (Ativan)

DRUG CLASS: Benzodiazepine; antianxiety/sedative hypnotic agent

RECEPTOR AFFINITY: Acts mainly at the subcortical levels of the central nervous system (CNS), leaving the cortex relatively unaffected. Main sites of action may be the limbic system and reticular formation. It potentiates the effects of α -aminobutyric acid, an inhibitory neurotransmitter. The exact mechanism of action is unknown.

INDICATIONS: Management of anxiety disorders or for short-term relief of symptoms of anxiety or anxiety associated with depression (oral forms). Also used as preanesthetic medication in adults to produce sedation, relieve anxiety, and decrease recall of events related to surgery (parenteral form). Unlabeled parenteral uses for management of acute alcohol withdrawal.

ROUTE AND DOSAGE: Available in 0.5-, 1-, and 2-mg tablets; 2 mg/mL concentrated oral solution and 2 mg/mL and 4 mg/mL solutions for injection.

Adults: Usually 2–6 mg/day orally, with a range of 1–10 mg/day in divided doses, with the largest dose given at night. 0.05 mg/kg intramuscularly (IM) up to a maximum of 4 mg administered at least 2 h before surgery. Initially 2 mg total or 0.044 mg/kg intravenously (IV) (whichever is smaller). Doses as high as 0.05 mg/kg up to a total of 4 mg may be given 15–20 min before the procedure to those benefiting by a greater lack of recall.

Geriatric patients: Dosage not to exceed adult IV dose. Orally, 1–2 mg/day in divided doses initially, adjusted as needed and tolerated.

Children: Drug should not be used in children younger than 12 years.

HALF-LIFE (PEAK EFFECT): 10–20 h (1–6 h [oral]; 60–90 min IM; 10–15 min IV).

SELECTED ADVERSE REACTIONS: Transient mild drowsiness, sedation, depression, lethargy, apathy, fatigue, light-headedness, disorientation, anger, hostility, restlessness, confusion, crying, headache, mild paradoxical excitatory reactions during first 2 weeks of treatment, constipation, dry mouth, diarrhea, nausea, bradycardia, hypotension, cardiovascular collapse, urinary retention, and drug dependence with withdrawal symptoms.

WARNINGS: Contraindicated in psychoses; acute narrow angle glaucoma; shock; acute alcoholic intoxication with depression of vital signs; and during pregnancy, labor and delivery, and while breastfeeding. Use cautiously in patients with impaired liver or kidney function and those who are debilitated. When given with theophylline, there is a decreased effect of lorazepam. When using the drug IV, it must be diluted immediately before use and administered by direct injection slowly or infused at a maximum rate of 2 mg/min. When giving narcotic analgesics, reduce its dose by at least half in patients who have received lorazepam.

SPECIFIC PATIENT AND FAMILY EDUCATION

- Take the drug exactly as prescribed; do not stop taking the drug abruptly.
- Avoid alcohol and other CNS depressants.
- Avoid driving and other activities that require alertness.
- Notify the prescriber before taking any other prescription or over-the-counter drug.
- Change your position slowly and sit at the edge of the bed for a few minutes before arising.
- Report to the prescriber any severe dizziness, weakness, drowsiness that persists, rash or skin lesions, palpitations, edema of the extremities, visual changes, or difficulty urinating.

Telephone Hotlines

Public and private funding and the efforts of trained volunteers permit most communities to provide crisis services to the public. For example, telephone hotlines for problems ranging from child abuse to suicide are a part of health delivery systems of most communities. Crisis services permit immediate access to the mental health system for people who are experiencing an emergency (such as threatened suicide) or for those who need help with stress or a crisis.

Residential Crisis Services

Many communities provide, as part of the health care network, residential crisis services for people who need short-term housing. The specific residential crisis services available within a community reflect the problems that the community members judge as particularly important. For example, some communities provide shelter for teenage runaways; others offer shelter for abused spouses. Still others provide shelter for people who would otherwise require acute psychiatric hospitalization. These settings provide residents with a place to stay in a supportive, home like atmosphere. The people who use these services are linked to other community services such as financial aid.

Evaluation and Treatment Outcomes

Outcomes developed in cooperation with the person experiencing the crisis guide the evaluation. Once assessment data are clustered and prioritized and the outcomes are determined. Once interventions are developed and implemented in cooperation with the individual in crisis, the person should come through the crisis with improved health, well-being, and social function. If complications occur, the nurse should make appropriate alterations in the entire nursing process or make appropriate referrals.

LOSS, GRIEF, AND BEREAVEMENT

Loss, grief, and bereavement are universal human experiences. The terms bereavement and mourning are used interchangeably to describe the process of healing after a perceived loss. The outcomes of loss, grief and bereavement can range from an increase in psychosocial functioning to maladaptation which can include death, illness, isolation, and/or mental illness. Nurses are important caregivers who are called upon to provide support and guidance during these difficult times. This section focuses on the loss of a loved one.

KEYCONCEPT **Loss** can evoke minor to complex thoughts, feelings, and behaviors depending on the perceived relationship of the person with the lost loved object or person.

In death, the intensity of the loss is based on perceived relationship to the deceased and the circumstances of the loss. Death can be sudden and unexpected or after a long-term, chronic illness. Stigmatic losses (death associated with a stigmatized event or action such as abortion, AIDS, homicide, and suicide) can also affect coping with and healing after a loss.

The first year after a loss is considered to be the most difficult as holidays, birthdays, anniversaries, and other important life events must be handled by the bereaved. Days surrounding the anniversary date of the death can be difficult for the bereaved.

KEYCONCEPT **Grief** is a natural, intense, physical, emotional, social, cognitive, or social reaction to the death of a loved one. Spontaneous expressions to loss can include sobbing, crying, anger, and expressions of guilt.

Grief

There are commonalities in grief, but each grief experience is specific to the unique relationship that is lost. While grief is usually associated with death, it can occur without a death and be unrecognized. **Predeath grief** occurs prior to a death such as when a loved one has a terminal illness. The grief symptoms can be severe and are most likely to occur in caregivers of patients at the end of life, particularly dementia patients. Higher predeath grief levels are associated with depressive symptoms, caregiver burden, and less communication within the family about dying. **Acute grief** occurs immediately after the death of a loved one and normally evolves to a permanent state of integrated grief after a process of adaptation. *Integrated grief* is a long-term process where there continues to be mild yearning and other painful emotions, thoughts, and memories, but they are not intrusive. Even though there may be occasional periods of grief intensity, they do not interfere with ongoing life and a sense of well-being. Failure to adapt to the loss can lead to a prolonged grief disorder (PGD) (intense longing for or persistent preoccupation with the deceased that lasts more than 6 months) (Meichsner et al., 2020).

Theories of Bereavement

KEYCONCEPT Bereavement is the process of healing and learning how to cope with the loss. It begins immediately after the loss, and can last months or years. Individual differences, age, religious and cultural practices, and social support influence grief and bereavement.

Stage Theories

There has been wide acceptance that bereavement follows stages (Bowlby & Parkes, 1970; Kubler-Ross, 1969). Although over time, the stage theory of grief and bereavement has been challenged and remains unsupported by empirical evidence, it continues to be used by health care professionals (Corr, 2018; Meichsner et al., 2020).

Dual Process Model

The **dual process model** (DPM) offers a nonlinear explanation of how grieving persons and families come to terms with their loss over time (Stroebe et al., 2010; Stroebe & Schut, 2015). This model can be used to understand how bereaved individuals cope (Fiore, 2019). According to DPM, the person adjusts to the loss by oscillating between **loss-oriented coping** (preoccupation with the deceased) and **restoration-oriented coping** (preoccupation with stressful events as a result of the death including financial issues, new identity as a widow[er]). **Oscillation** is the process of confronting (loss-oriented coping) and avoiding (restoration-oriented coping) the stresses associated with bereavement. At times, the bereaved person is confronted with the loss and memories, and at other times, the person will be distracted and the thoughts and memories will be avoided. The bereaved experiences relief from the intense emotion associated with the loss by focusing on other things. For example, the bereaved person may be recalling a special moment in the relationship such as a wedding or imagining what the person would say about a current event but then switches to thinking about completing tasks that the deceased had previously undertaken (e.g., paying bills, cooking meals). In the loss-oriented coping mode, emotions relate to the relationship with the deceased person; in the restoration-oriented coping, the bereaved person's emotions relate to the stressful events associated with the responsibilities and changes as a result of the loss. Over time, after repeated confrontation with the loss, there is no longer a need to think about certain aspects of the loss (Currie et al., 2019) (see [Figure 21-2](#)).

Figure 21-2: Dual process model of coping with bereavement. (Redrawn from

Stroebe, M., & Schut, H. (1999). The dual process model of coping with bereavement: Rationale and description. *Death Studies*, 23, 213. Used with permission from Taylor & Francis Ltd, <https://www.tandfonline.com>)

Types of Bereavement

Uncomplicated Bereavement

Most bereaved people experience **uncomplicated bereavement** after the loss of a loved one. Uncomplicated bereavement grief is painful and disruptive, however, there is always movement. Questions surface such as “Why did the death happen?” “Why my loved one?” “Why me?” and, “Why did God allow this to happen?”

The bereavement process is often applied to other situations in which a loss occurs, not necessarily the death of a person. The “empty nest syndrome,” divorce, birth of a handicapped child, and death of a pet are other examples of losses where there may be grief and bereavement.

Most bereaved persons do not need clinical interventions and are able to find new meaning and purpose in their lives. Their self-esteem and sense of competency while threatened remain intact. They gradually accept the sense of loss as a reality and are able to move on with their lives. There is little evidence they need or benefit from counseling or therapy. Those who experience suicidal thoughts with a plan and/or suicidal gestures should be evaluated for depression and posttraumatic stress disorder (PTSD) (Hamdan et al., 2020).

Traumatic Grief

Traumatic grief is a term that is used for a more difficult and prolonged grief. In traumatic grieving, external factors influence the reactions and potential long-term outcomes. For example, memories of the traumatic death of the deceased may lead to more traumatic memories including the violent death scene/ The external circumstances of death associated with traumatic grief include (1) suddenness and lack of anticipation; (2) violence, mutilation, and destruction; (3) degree of preventability or randomness of the death; (4) multiple deaths (bereavement overload); and (5) mourner’s personal encounter with death involving a significant threat to personal survival or a massive and shocking

confrontation with the death (or mutilation) of others (Zetumer et al., 2015).

The deaths of COVID-19 victims are expected to leave several million bereaved families and friends who are high risk for traumatic grief. Funeral ceremonies are suspended. Families are deprived of assisting the dying person because of the contagiousness of the disease. Families are unable to visit loved ones in the hospitals and intensive care units (ICU) which can lead to feelings of guilt. As a result of these factors, an increase in traumatic bereavement and PGD is expected. The multiple deaths of the COVID-19 family members could lead to bereavement overload (Kokou-Kpolou et al., 2020).

Complicated Bereavement

Complicated bereavement or PGD occurs in about 10% to 20% of bereaved persons (Skritskaya et al., 2020). The person is frozen or stuck in a state of chronic mourning which lasts for more than a month to 6 months after a loss. In other words, there is no movement in the thought processes in how the bereaved view and experience their loss. The person may feel bitter over the loss and wish their life could revert to the time they were together.

In complicated grief there is an intense longing and yearning for the person who died that lasts for more than 6 months. Additionally, the person may have trouble accepting the death, an inability to trust others since the death, excessive bitterness related to the death, and feeling that life is meaningless without the deceased person. Individuals who are more vulnerable for developing complicated bereavement are those who have experienced a sudden, unexpected loss, stigmatic loss, or death of a loved one after a long-term chronic illness as these situations have the potential to limit their social support.

Teamwork and Collaboration: Working Toward Recovery

The person with uncomplicated grief may not need mental health team intervention. When grief and bereavement become complicated with ongoing psychological and physical stress, mental health interventions can support an adaptive response to the loss. A priority of concern is always safety. Are there

thoughts of suicide? Is depression evident? The individual may need support from a psychiatrist, nurse, psychologist, social worker, counselor or chaplain.

EVIDENCE-BASED NURSING CARE OF PERSON IN GRIEF

Mental Health Nursing Assessment

The initial assessment determines whether the individual is experiencing predeath grief, acute grief, or complicated bereavement. In predeath grief, the terminally ill loved one is alive, but the caregiver has intense sadness, anger, and loneliness over the changes in the relationship with the patient, loss of shared activities, and plans for the future. In acute grief, there are bouts of yearning, sadness and other painful emotions that are frequently intense. There may be intrusive thoughts and memories and heightened reaction to reminders of the loss. In complicated bereavement, the loss occurred at least 6 months prior, daily functioning is impaired with thoughts, yearning and memories of the deceased with evidence of difficulty accepting the loss. Emotional pain exists longer than socially acceptable (Meichsner et al., 2020).

Physical Health

The status of physical health will provide clues to the intensity of the grief. Sleep difficulty, lack of appetite, weight loss can indicate the severity of the grief. Substance use should be determined. One area to determine is how dependent the bereaved was on the deceased for physical care. Who prepared the meals, shopping, or house cleaning?

Cognitions

The thought process should be assessed for negative and maladaptive thoughts. If the person is protesting the death (death should not have happened; it is not fair; could have prevented death) and has a negative view of the world (bad

things happen; no one is safe), they are at risk maladaptive thoughts that complicate bereavement. An example of other negative cognitions includes needing the person (i.e., life is unbearable without the person who died) (Skritskaya et al., 2020).

Emotional and Behavioral Responses

Assessing the persons emotional state includes determining current mood and behavior. Poor grooming, disheveled appearance, blank or tearful facial expressions could indicate depression. A suicide risk assessment should be conducted. By asking the question, “Have you wished that you were dead or wished that you could go to sleep and not wake up?”, the nurse can determine if further suicide risk assessment should be completed and the patient referred to a therapist (see [Chapters 22](#) and 25).

Social Functioning and Support

Determining the presence of social support is important as well as determining the level of social functioning. Withdrawal from normal social activities or failure to resume previous activities may indicate the onset of depression.

Clinical Judgment

Patient safety is always a priority. If the patient answers “yes” to suicide risk questions, the individual should be referred. If patient is safe, physical health such as eating and sleeping should be addressed. If there are changes in these areas, the nurse should consider depression or an environmental situation such as lack of ability to shop for food as a priority. For an older adult who has lost a spouse or partner, living arrangements could be considered. In many instances, grief may lead to depression because of social isolation and loneliness. Can the bereaved carry out activities of daily living and personal safety without the deceased? Helping the person manage physical health needs could be a priority.

Therapeutic Relationship

A positive therapeutic relationship is critical for the bereaved person who is grieving. The loss of attachment of a loved one leads to pain and emptiness that will take time to heal. A calm, empathic, quiet approach of acceptance of the person's level of pain will promote interaction. Providing an opportunity to share memories about the deceased is not only comforting, but helps to accept the loss. Listening is key. It is important to avoid giving reassurance that everything will be fine. It is appropriate to normalize the grief by reassuring the person that sadness and yearning are normal. Keeping an open, non-judgmental attitude will allow the person to express feelings in a safe environment (Meichsner et al., 2020).

Mental Health Nursing Interventions

The goal of bereavement interventions is to help the person adapt and re-stabilize biopsychosocial systems as the pain and sadness lessens with time. Adaptation involves accepting the reality of the loss and restoring a sense of well-being (Meichsner et al., 2020).

Self-Care

Self-care strategies can range from providing or arranging for physical care for the person to suggesting resources. Adequate nutrition and sleep are critical to support the person through bereavement. Strategies include recommending balanced meals and teaching sleep hygiene techniques.

Medications

Short-term reliance on antidepressants or sleep aids may be useful during acute grief. Careful monitoring of the use of medications is needed to prevent long-term use of these medication.

Counseling

Counseling is very beneficial to individuals experiencing a loss. The counseling goal is to foster adaptive coping and management of painful experiences. The focus of the counseling will be determined by the circumstances of the loss and the relationship of the bereaved to the deceased. If a person is experiencing predeath grief, the nurse identifies the changes associated with the disease and fosters acceptance of the loved one's disease and symptoms. The nurse continues to monitor the health and well-being of the caregiver who may be unaware of the extent of their grief or the toll on their own health. For someone experiencing acute grief, in addition to normalizing the painful, sad feelings, the counseling approaches can encourage engagement with a natural support system or grief support group, and focus on ways to live with the reminders of the loss. If prolonged grief is the primary characteristic with impaired functioning and preoccupation with thoughts of the deceased, the person should be referred to a mental health specialist for further evaluation (Meichsner et al., 2020).

Social Support Strategies

Bereavement can be a highly stressful time with increased physical and psychological demands. This is a time that the bereaved benefit from the support of family, friends, social cultural, and religious communities. Normal life is suspended and a new reality gradually evolves. Social support is especially needed after the busy time of planning a funeral or celebration of life is over and the social community gradually withdraws. Loneliness sets in and the full impact of the loss is realized. During this time, the person is high risk for suicide. Through social support, the individual can begin thinking about their future and focus on their own self-care and well-being.

The COVID-19 pandemic greatly complicates the grieving process for many because of the lack of face-to-face social support for the surviving family members. Not only were they unable to assist their loved one in dying, they do not have access to social support because of restrictions. A priority for family and friends is to find ways to maintain social contacts such as taking advantage of small gatherings or enjoyable activities.

Evaluation and Treatment Outcomes

A positive outcome of bereavement is adaptation to a life without the deceased, but learn to live with the reminders of the deceased. Other positive outcomes include attending to self-care and enjoying social and recreational activities again.

DISASTER AND TERRORISM

A disaster is a sudden ecologic or human-made phenomenon that is of sufficient magnitude to require external help to address the psychosocial needs as well as the physical needs of the victims. Acts of terrorism and pandemics present situations that mimic disasters and are categorized disasters.

KEYCONCEPT A **disaster** is a sudden overwhelming catastrophic event that causes great damage and destruction that may involve mass casualties and human suffering requiring assistance from all available resources.

Although disasters can affect all members of a society, the most affected are the victims and survivors of the event, as well as nurses and others who are first to respond to the traumatic and life-threatening consequences of the event. The mental health of the survivors of disasters can be severely impacted by the event. Fear, anger, and distress elevate severe anxiety to the panic level, which can result in severe mental illnesses. Unresolved crisis or disastrous events can lead to disorganized thinking. Post-disaster depression is a real risk (North et al., 2018). In addition, the victims may experience the development of acute stress disorder (which has a strong emphasis on dissociative symptoms) and PTSD.

Historical Perspectives of Disasters in the United States

Throughout history, disasters have been portrayed from a fatalistic perspective that humans have little control over catastrophic events. Some cultures contend that natural disasters are acts of God. Other cultures express their belief that

natural disaster events can be attributed to gods dwelling within places such as volcanoes, with eruptions being an expression of the gods' anger. Although often caused by nature, disasters can have human origins. Wars and civil disturbances that destroy homelands and displace people are included among the causes of disasters. Other causes include a building collapse, blizzard, drought, earthquake, epidemic, explosion, famine, fire, flood, hazardous material or transportation incident (such as a chemical spill), hurricane, nuclear incident, terrorist attack, and tornado. Often, the unpredictability of such disasters causes fear, confusion, and stress that can have lasting effects on the health of affected communities and their sense of well-being.

Natural Disasters

The busy Atlantic hurricane season of 2020, Hurricane Maria in Puerto Rico in 2018, Hurricane Harvey in Texas in 2017, and the earthquake and tsunami in Japan in 2011 highlight the importance of government preparedness for natural disasters as well as terrorism. In the United States, the lack of government response and breakdown in communication during Maria resulted in thousands of hurricane victims being displaced and injured. Many Puerto Ricans moved to Florida and experienced more emotional and psychological problems than those staying on the island (Scaramutti et al., 2019). The Japan disaster became a cascade of disasters, resulting in the death of thousands of residents and contamination from the damaged nuclear site. Consequences of these disasters will still be occurring months and years after the initial events.

Terrorism

In recent history, we have experienced several attacks of violence and terrorism that are unprecedented in North America. Some examples are the Pittsburgh synagogue in 2019, destruction of the World Trade Center in New York on September 11, 2001, the Sandy Hook school tragedy in 2012, and the Boston Marathon bombing in 2013, all of which shattered North Americans' sense of safety and security.

Since September 11, 2001, the emergency response planning of federal, state, and local agencies has focused on possible terrorist attacks with chemical,

biologic, radiologic, nuclear, or high-yield explosive weapons. Before September 11, 2001, government agencies and public health leaders had not incorporated mental health into their overall response plans to bioterrorism. But in the aftermath of the mass destruction of human life and property in 2001, government and health care leaders are recognizing the need for monumental mental health efforts to be implemented during episodes of terrorism and disaster. The psychological and behavioral consequences of a terrorist attack are now included in most disaster plans.

COVID-19 Pandemic

In December 2019, the Wuhan Municipal Health Commission announced an outbreak of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The virus quickly spread globally and in 2020, World Health Organization (WHO) declared COVID-19 a pandemic and the United States declared a National Emergency. In the U.S., an unprepared health care system was quickly overloaded with critically ill patients who needed ICU beds that did not exist. There was a lack of prepared health care workers who were quickly overwhelmed. Mortality rates are high, especially among the older adults and those with comorbidities. Health care and public health care systems are trying to confront this disease around the globe.

While classified as a disaster, COVID-19 is different than a natural disaster that is time-limited. The physical and psychosocial consequences for the affected persons, survivors, health care workers, and community are unprecedented. The effects will be felt for many years and societies will be forever changed.

The mental health of survivors and health care workers is expected to be another “unseen epidemic” (Stawicki et al., 2020). For patients who survive the disease, they may have life-long mental health problems, isolation and stigma. The psychosocial stressors, particularly related to the use of isolation/quarantine, fear and vulnerability are affecting the total community (Torales et al., 2020).

Health care workers are particularly vulnerable to emotional distress because of their risk of exposure to the virus, concern about infecting and caring for their loved ones, shortages of personal protective equipment, longer work hours and involvement in ethical resource allocation (Pfefferbaum & North, 2020). Health care workers are reporting depression, anxiety, insomnia, and PTSD (Lai et al., 2020; Yin et al., 2020).

Phases of Disaster

Long-term mental health consequences are evident in most disasters. Natural and human-made disaster can be conceptualized in three phases:

1. *Prewarning of the disaster.* This phase entails preparing the community for possible evacuation of the environment, mobilization of resources, and review of community disaster plans. In some disasters, such as in the 2011 earthquake in Japan, there is very little warning. In other instances, such as the COVID-19 pandemic, there were unheeded warnings more than a decade before the disease appeared.
2. *The disaster event occurs.* In this phase, the rescuers provide resources, assistance, and support as needed to preserve the biopsychosocial functioning and survival of the victims. In large disasters, the rescuers and health care professionals also experience the traumatic event as both residents and health care providers. The victims experience the initial trauma and threats that occur immediately after the disaster such as confusion (communication breakdown), lack of safety (no available law enforcement), and lack of health care services.
3. *Recuperative effort.* In the third phase, the focus is on implementing strategies for healing sick and injured people, preventing complications of health problems, repairing damages, and reconstructing the community. The disruption effects can be traumatic to the community residents. The debris, lack of trust of the government, fragmentation of families, financial problems, lack of adequate housing, inadequate temporary housing, and fear of another disaster contribute to the long-term negative effects of disasters.

Responses to Disaster

Psychiatric nurses encounter three different types of disaster victims. The first category is the victims who may or may not survive. If they survive, the victims often experience severe physical injuries. The more serious the physical injury, the more likely the victim will experience a mental health problem such as PTSD, depression, anxiety, or other mental health problems (Osofsky et al., 2018). Victims and families need ongoing health care to prevent complications related to both their physical and mental health (Sledge & Thomas, 2019).

The second category of victims includes the professional rescuers. These are

persons who are less likely to experience physical injury but who often experience psychological stress. The professional rescuers, such as police officers, firefighters, nurses, and so on, have more effective coping skills than do volunteer rescuers who are not prepared for the emotional impact of a disaster. However, many professional responders report experiencing PTSD for many months after the traumatic event in which they were involved (Lewis-Schroeder et al., 2018).

The third category includes everyone else involved in the disaster. Psychological effects may be experienced worldwide by millions of people as they experience terrorism or disaster vicariously or as direct victims of the terrorism/disaster event. After an act of terrorism, most people will experience some psychological stress, including an altered sense of safety, hypervigilance, sadness, anger, fear, decreased concentration, and difficulty sleeping. Others may alter their behavior by traveling less, staying at home, avoiding public events, keeping children out of school, or increasing smoking and alcohol use. After Hurricane Maria, most of Punta Santiago was without electrical power, and more than half of the households sustained severe damage. In the aftermath, schools were closed, jobs were lost. Families were subject to diseases, dependency on aid, and exposure to heat and humidity. Two-thirds of residents surveyed reported an increase in the significant symptoms associated with depression, generalized anxiety, or posttraumatic stress (Ferré et al., 2018) (see [Box 21-4](#)).

BOX 21.4

Health Outcomes after Disaster for Older Americans

Bell, S. A., Horowitz, J., & Iwashyna, T. J. (2020). *Health outcomes after disaster for older adults with chronic disease: A systematic review*. *The Gerontologist*, 60(7), e535–e547.
<https://doi.org/10.1093/geront/gnz123>

THE QUESTION: Are there associations among disease outcome after weather- and climate-related disasters among older adults?

METHODS: A systematic review of studies on clinical outcomes of four chronic diseases (COPD), end-stage renal disease (ESRD) congestive heart failure (CHJF) and diabetes after disaster exposure.

FINDINGS: Three disasters were the focus of the findings – earthquakes, hurricanes, and wildfires. The outcomes include access to health care and post disaster health care utilization. The review showed that disasters have limited or insignificant effects older adults relative to younger population.

IMPLICATIONS FOR NURSING: Emergency planning and health services for the older adult with multiple chronic conditions remain important to the health of the older adult.

Teamwork and Collaboration: Working Toward Recovery

The role of the behavioral health care worker in disasters, specifically a nuclear detonation in a U.S. city is the support of lifesaving activities and the prevention of additional casualties from fallout. Victims experiencing head injuries or psychic trauma after a disaster may have to be hospitalized. During a disaster, a victim with a mental illness may experience regression to their pretreatment condition. If community mental health facilities are available, they should be directed to seek assistance from mental health care professionals. The victims should receive follow-up care for the disaster response.

EVIDENCE-BASED NURSING CARE OF PERSONS EXPERIENCING DISASTERS

Mental Health Nursing Assessment

The nurse should assess the kind and severity of a natural or human-made disaster or terrorist act to determine the capability of individuals and communities to respond in a supportive way. Assessment includes the ages of the victims, gender, their capability to participate in problem-solving activities related to the devastation left by the disaster, and their level of self-confidence or self-esteem. The nurse should maintain a calm demeanor, obtain and distribute information about the disaster and the victims, and reunite victims and their families. In addition, there is a need to monitor the news media's impact on the mental health of the victims of the crisis. Sometimes the persistence of the news media diminishes the ability of the survivors to achieve closure to the crisis. Constant rehashing of the disaster in the newspapers, television, and online can initiate feelings of anxiety and depression, or increase and prolong the severity of these feelings (van der Velden et al., 2018).

Women exhibit higher levels of distress than men after a disaster, especially pregnant women and older women. Children are especially vulnerable to disasters and respond according to their ages and family experiences. Traumatized children and adolescents are high-risk victims of a wide range of

behavioral, psychological, and neurologic problems after experiencing various traumatic events (Blake & Fry-Bowers, 2018).

Physical Health

The nurse should assess physical reactions that may involve many changes in body functions, such as tachycardia, tachypnea, profuse perspiration, nausea, vomiting, dilated pupils, and extreme shakiness. Virtually any organ may be involved. Some victims may exhibit panic reactions and loss of control and have a total disregard for their personal safety. The victims may be suicidal or homicidal and are at high risk for injuries that may include infection, trauma, and head injuries. During the rescue, medical care is a priority. Any medical or psychiatric disorders should be assessed and information communicated to the rest of the health care team. Unexplained physical symptoms such as headache, fatigue, pain, chest pain, and gastrointestinal disturbances should be included in the assessment.

Mental Status

During a disaster, fear and hopelessness can immobilize victims. The victims may suffer from loss of feelings of well-being and various psychological problems, including panic responses, anxiety, and fear. Dissociation and fear are predictive of later developing PTSD and depressive symptoms. Victims witnessing others suffer are especially at high risk for future mental health problems and should be assessed for the details of the disaster (Su et al., 2020).

Emotional and Behavioral Responses

The survivors of the disaster may experience traumatic bereavement because of their feelings of guilt that they survived the disaster (Droždek et al., 2020). Responses to psychological distress need to be differentiated from any psychiatric illness that the person may be experiencing. A response to a disaster may leave the person feeling overwhelmed, incapacitated, and disoriented.

The victims should be assessed for behaviors that indicate a depressed state, presence of confusion, uncontrolled weeping or screaming, disorientation, or aggressive behavior. Ideally, the nurse should assess the coping strategies the victim uses to normally manage stressful situations.

Social Support and Functioning

Cultural values and beliefs help define the significance and meaning of a disaster. In some instances, a disaster can slow development, but usually the customs, beliefs, and value systems remain the same. It is important that first responders and health care teams are sensitive to the cultural and religious beliefs of the community. In many instances, victims' spiritual beliefs and religious faith help them cope with the disaster.

In a disaster, the victims may experience economic distress because of job loss and loss of other resources. This may ultimately lead to psychological distress. In addition, acts of aggression and other mental health problems may emerge (Daks et al., 2020). Again, shelter, money, and food may not be available. The absence of basic human needs such as food, a place to live, or immediate transportation quickly becomes a priority that may precipitate acts of violence.

Clinical Judgment

Because the responses to disaster are so varied, assessment data are critical. What is the disaster -tsunami, terrorism, or pandemic? Priorities for acutely effected persons are maintaining life systems and treating physical. Depending on the long-term impact of the disaster and the type of disaster, nurse will identify coping skills, support systems, and referral sources.

Therapeutic Relationship

Therapeutic communication is key to understanding the extent of the psychological responses to a disaster and to establishing a bridge of trust that communicates respect, commitment, and acceptance. Developing rapport with

the victim communicates reassurance and support.

Mental Health Nursing Interventions

The goals of care include helping the victims prioritize and match available resources with their needs, preventing further complications, monitoring the environment, disseminating information, and implementing disease control strategies. People with pre-existing mental health conditions should continue with their treatment plans during an emergency and monitor for any new symptoms (Centers for Disease Control and Prevention [CDC], 2019). The focus of nursing interventions is on the individual, family, and community.

Self-Care

Any physiologic problems or injuries should be treated quickly. During the emergency response, individuals will be triaged to the appropriate level of care. Victims who are primarily distressed and may have somatic symptoms will be treated after those suffering from exposure with critical injuries. The primary public health concern is clean drinking water, food, shelter, and medical care. In natural disasters, contaminated water and food and lack of shelter and medical care may worsen illnesses that already exist. In pandemics, the primary public health concern is stopping the spread of the disease which means isolation of infected person and quarantine of contacts. For communities, a pandemic means mass home-confinement directives – new to Americans.

All patients, families and communities need to be reassured of the caring and commitment of the nurse to their safety, comfort, and well-being throughout the triage process. Ideally, a mental health specialist is an integral member of the triage team. Many of the same interventions used for persons experiencing stress or crisis will be used for these victims. See also Chapter 33 for discussion of somatization. Victims should be encouraged to do necessary chores and participate in decision-making.

Medications

During the treatment process for the psychological consequences of the disaster, it may become necessary to administer an antianxiety medication or sedative, especially in the early phases of recovery.

Counseling

After the initial interventions, the nurse should support the development of resilience, coping, and recovery while providing technical assistance, training, and consultation. A useful model is the **ABCs of psychological first aid** that focuses on A (arousal), B (behavior), and C (cognition). When arousal is present, the intervention goal is to decrease excitement by providing safety, comfort, and consolation. When abnormal or irrational behavior is present, survivors should be assisted to function more effectively in the disaster, and when cognitive disorientation occurs, reality testing and clear information should be provided. In the initial phases, the nurse should assist the victim in focusing on the reality of problems that are immediate, with specific goals that are consistent with available resources as well as the culture and lifestyle of the victim.

Debriefing (the reconstruction of the traumatic events by the victim) may be helpful for some. Long a common practice, debriefing was believed to be necessary in order for the person to develop a healthy perspective of the event and ultimately prevent PTSD. However, debriefing is not useful for everyone. Additionally, cultural groups respond differently to traumatic events. Therefore, compulsory debriefing is not recommended. If the victim has symptoms of PTSD, referral to a mental health clinic for additional evaluation and treatment is important (see Chapter 29).

The nurse should prepare the victim for recovery by teaching about the effects of stress and helping the victim identify personal strengths and coping skills. Positive coping skills should be supported. The victims should be encouraged to report any depression, anxiety, or interpersonal difficulty during the recovery period. After most disasters, support groups are established that help victims and their families deal with the psychological effects of the disaster.

Psychoeducation

When the nurse explains anticipated reactions and behaviors, this helps the victims gain control and improve coping. For example, after a major disaster, they may have excessive worry, preoccupation with the event, and changes in eating and sleeping patterns. With time, counseling, and group work, these symptoms will lessen. Active coping strategies can be presented in multiple media forums, such as television and radio. After the initial shock, victims react by trying to do something to resolve the situation. When victims begin working to remedy the disaster situation, their physical responses become less exaggerated, and they are more able to work with less tension and fear.

Educating the public about the natural recovery process is important. Information gaps and rumors add to the anxiety and stress of the situation. Giving information and direction helps the public and victims to use the coping skills they already possess. Initially, the event may leave individuals and families in a stage of ambiguity with frantic, disorganized behavior. In addition, individuals and family members are concerned about their own physical and psychological responses to the disastrous event.

Community Care

Outreach is especially important because research shows that disaster victims do not access mental health systems. Peer-delivered mental health services are especially effective in identifying and connecting with victims, especially those with predisaster psychiatric problems (Cheng et al., 2020).

Family support systems may need to be reestablished. The health care community should actively reach out to the media and keep the press engaged. Direct attention to stories that inform and help the public respond should be encouraged. Some federal agencies assist victims of disasters. This assistance is available for individual, families, and communities. One of these agencies is the Federal Emergency Management Agency (FEMA). When a disaster occurs, FEMA sends a team of specialists who review the devastation of disaster. They provide counseling and mental health services and arrange for many of the victims to access other services needed for survival, including training programs. In addition, the Substance Abuse and Mental Health Services Administration (SAMHSA) of the Department of Health and Human Services is available to assist both victims of and responders to the disaster. When a disaster disrupts the victim's social network, other resources must be made available for social

support.

The social support system provides an environment in which the victims experience respect and caring from the caregivers, the opportunity to ventilate and examine personal feelings regarding the tragedy, and the opportunity to begin the healing and recovery process. Supporting the development of more contacts within the social network can be done by organizing support groups within the area of the disaster that address grief and loss, trauma, psychoeducational needs, and substance abuse. In addition, the nurse may refer the victims to nearby support groups or religious groups that are appropriate to meet their needs.

Evaluation and Treatment Outcomes

To determine the effectiveness of nursing interventions, the nurse should evaluate the outcomes based on the success of resolution of the disaster. The outcomes will depend on the specific disaster and its meaning (appraisal) to the survivors. For example, are the survivors in a safe place? Are the victims able to cope with the disaster? Were the appropriate supports given, so the victims could draw upon their own strengths?

SUMMARY OF KEY POINTS

- A crisis is a time-limited event that occurs when coping mechanisms fail to provide adaptive skills to address a perceived challenge or threat.
- Grief is a natural, intense physical, emotional, social, and cognitive responses to loss, and bereavement is the process of healing after a loss. The variations in grief are influenced by the characteristics of the individual, perceived relationship to the deceased, and the type of loss.
- Stage theories propose that grief and bereavement follow stages/phases. Process models explain bereavement as nonlinear.
- For most persons, bereavement is uncomplicated and there is no need for counseling. Complicated grief occurs in about 10% to 20% of bereaved

persons. Interventions such as medication, counseling, and/or a support group may be required for this group.

- Interventions are designed to support people through crises by helping them understand the process of recovery and identify the resources they need and how to get them.
- Disaster is a sudden, overwhelming catastrophic event that causes great damage and may cause mass casualties and human suffering that require assistance from all available resources.
- COVID-19 pandemic is a global disaster that is unprecedented in contemporary times. Psychological consequences effect the individual, family and community.
- Depending on the disaster, interventions are provided to individuals, families, and communities.

CRITICAL THINKING CHALLENGES

1. Compare nursing interventions used for crises, bereavement, and disasters. What are the similarities? What are the differences?
2. After the death of his mother, a 24-year-old single man with bipolar disorder moves into an apartment. He continues to take his medication but feels sad about his mother's death. He is not adjusting well to living alone and tells his nurse that he no longer wants to go to work and feels he would be better off if he joined his mother. The nurse generates the following supporting positive coping related to inadequate support system. Develop a plan of care for this young man.
3. Listen to people who have experienced a loss to determine where they are in the bereavement process. Discuss the role of medication and counseling when used in crisis or bereavement.
4. Compare uncomplicated bereavement to complicated bereavement. How would you recognize the difference? When would it be appropriate to refer a bereaved person to a support group or mental health specialist?
5. There is a terrorist threat in your community. A patient appears in the emergency department convinced he is going to die. How would you proceed with assessing this patient?

5. A patient is recently diagnosed with COVID-19. She refused the vaccine because she does not believe in vaccines. She is showing fear of her treatment and guilt about not taking the vaccine because she is afraid that she has transmitted the disease to her family. What is the first priority in providing her care once she is medically stable?

Unfolding Patient Stories: George Palo

Part 1 (Loss of Wife and Dog)

George Palo, 90 years old, was diagnosed 6 months ago with minor neurocognitive disorder,

Alzheimer's type. He lives independently in an apartment within a retirement community. His wife of 65 years died 3 years ago. He was managing well until the recent loss of his 13-year-old dog. What responses and behaviors associated with bereavement should the nurse consider when assessing him? How can his cognitive disorder complicate the process of grieving? How can the nurse guide his progression through grief and bereavement?

Movie Viewing Guides

Grace Is Gone (2007): Stanley Phillips (John Cusack) is a manager of a home-supply store and parent of two girls, 12-year-old Heidi (Shelan O'Keefe) and 8-year-old Dawn (Gracie Bednarczyk). His wife is a soldier in Iraq, but the viewers know her by her message left on the family answering machine. When an army captain and chaplain deliver the news that Grace had died bravely in combat, Stanley becomes numb. He impulsively takes his girls to wherever they desire—a theme park in Florida. Most of the movie follows the three on the trip and the father's attempt to delay and deny his wife's death.

VIEWING POINTS: Describe Stanley's reaction when he receives the news of his wife's death. What clues are present that Heidi gradually understands that something terrible has happened?

Suicide Prevention

Screening, Assessment, and Intervention

Rebecca Luebbert

KEYCONCEPTS

- hopelessness
- lethality
- suicide

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Identify suicide as a major mental health problem in the United States.
2. Define *suicide*, *suicidality*, *suicide attempt*, *parasuicide*, and *suicidal ideation*.
3. Describe population groups that have high rates of suicide.
4. Describe risk factors associated with suicide completion.
5. Identify key factors associated with specific suicide acts.
6. Describe evidence-based interventions used to reduce imminent and ongoing suicide risk.
7. Explain the importance of documentation and reporting when caring for patients who may be at risk of suicide.

KEY TERMS

- Acquired capability for suicide
- Case finding
- Commitment to treatment statement
- Ideation-to-action theories
- Parasuicide
- Perceived burdensomeness
- Suicidal ideation
- Suicidality
- Suicide attempt
- Suicide contagion
- Thwarted belongingness
- Volitional factors

INTRODUCTION

Suicide is one of the major health problems in the United States, accounting for more than 48,000 deaths in 2018 (American Foundation for Suicide Prevention [AFSP], 2020a). Suicide rates have steadily increased in the past 20 years, with a 35% increase in the total suicide rate from 1999 to 2018 (Hedegaard et al., 2020). The public health problem of suicidal behavior is so important that

several goals stated in *Healthy People 2020* and retained in *Healthy People 2030* directly target the reduction of deaths by suicide (U.S. Department of Health and Human Services [U.S. DHHS], 2020).

Suicide is so rejected in contemporary society that people with strong suicidal thoughts do not seek treatment for fear of being stigmatized by others. Reports and portrayals of suicide in the popular media and television further stigmatize those who consider or attempt suicide. Society's unwillingness to talk openly about suicide also contributes to the common misperceptions resulting in many myths regarding suicide (Corrigan et al., 2017; Oexle et al., 2020). [Box 22-1](#) presents several myths and facts about suicide.

Suicides are preventable deaths when immediate friends and family and health care providers identify symptoms and use effective interventions. All practicing nurses will come into contact with patients who are thinking about suicide and often can prevent suicides by identifying and intervening with those at risk. Through individual and public education, nurses also can do much to demystify suicide and reduce stigma for those at risk. To reduce the devastating public impact of suicide on those at risk and their families, nurses must be knowledgeable about suicide and be able to implement effective preventive interventions. This chapter contains tools that can be used to reduce the broad effects of suicide and provide appropriate care for patients who are suicidal.

Box 22.1

Myths and Facts about Suicide

Myth: Suicide only affects individuals with a mental health condition.

Fact: Many individuals with mental illness are not affected by suicidal thoughts, and not all people who attempt or die by suicide have mental illness.

Myth: Most suicides happen suddenly without warning.

Fact: Warning signs, verbally or behaviorally, precede most suicides.

Myth: People who die by suicide are selfish and take the easy way out.

Fact: Typically, people do not die by suicide because they do not want to live. People die by suicide because they want to end their suffering.

Myth: When people become suicidal, they will always be suicidal.

Fact: Active suicidal ideation is often short term and situation specific. While suicidal thoughts can return, they are not permanent.

Myth: Talking about suicide will lead to and encourage suicide.

Fact: Talking about suicide not only reduces the stigma but also allows individuals to seek help, rethink their opinions, and share their story with others.

Reprinted with permission from Fuller, K. (2020). Five common myths about suicide debunked.

<https://nami.org/Blogs/NAMI-Blog/September-2020/5-Common-Myths-About-Suicide-Debunked>

SUICIDES AND SUICIDE ATTEMPT

KEYCONCEPT is the voluntary act of killing oneself. It is a fatal, self-inflicted destructive act with explicit or inferred intent to die. It is sometimes called suicide completion.

This behavioral definition of suicide is limited and does not consider the complexity of potential underlying mental illness, personal motivations, and situational and family factors that provoke the suicide act. Except for the very young, suicide occurs in all age groups, social classes, and cultures (National Institute of Mental Health [NIMH], 2020).

The term **suicidality** refers to all suicide-related behaviors and thoughts of attempting or completing suicide and suicidal ideation. **Suicidal ideation** is thinking about and planning one's own death. In 2019, 4.8% of adults aged 18 and older had serious thoughts of suicide, with the highest prevalence among young adults aged 18 to 25 (11.8%) (NIMH, 2020). Population studies show that suicidal ideation varies depending on characteristics of the participants and the way suicidal ideation is measured. Although suicidal ideation often does not progress, having recurrent suicidal ideation is associated with poor mental health (Liu et al., 2020).

A **suicide attempt** is a nonfatal, self-inflicted destructive act with explicit or implicit intent to die. In 2018, an estimated 1.4 million Americans attempted suicide, with adult females reporting an attempt 1.4 times more often than males (AFSP, 2020). Suicidal ideation, previous psychiatric hospitalization, and a previous attempt are significant predictors of a completed suicide (Bostwick et al., 2016).

Parasuicide is a voluntary, apparent attempt at suicide, commonly called a suicidal gesture, in which the aim is not death (e.g., taking a sublethal drug). Parasuicidal behavior varies by intent. Some people truly wish to die, but others simply wish to feel nothing for a while. Still others want to send a message about their emotional state. Parasuicide behavior is never normal and should always be taken seriously.

KEYCONCEPT Lethality refers to the probability that a person will successfully complete suicide. Lethality is determined by the seriousness of the person's intent and the likelihood that the planned method of death will succeed. A plan to use an accessible firearm to commit suicide has greater lethality than a suicide plan that involves superficial cuts of the wrist.

Suicide is ranked as the tenth leading cause of death and accounts for 14.2 deaths per 100,000 population. On average, 132 Americans die by suicide each day, with a suicide occurring every 11 minutes in the United States: a rate of 132 completed successful suicides per day. Mountain regions have the highest rate of suicide (Fig. 22.1). Its overall prevalence may be underestimated because suicide can be disguised as vehicular accidents or homicide, especially in young people (AFSP, 2020; Centers for Disease Control and Prevention [CDC], 2020a).

Suicide Across the Life Span

Children, Adolescents, and Young Adults

Suicide is the second leading cause of death among those aged 10 to 34. Mental disorders can lead to poor performance in school, alcohol or other drug abuse, family discord, violence, and suicide. The most recent Youth Risk and Behavior Survey found that in the preceding year among high school students, 18.8% seriously considered attempting suicide, 15.7% made a suicidal plan, 8.9% attempted suicide, and 2.5% were seriously injured in a suicide attempt. Female students were more likely to attempt suicide (11.0%) than male students (6.6%), though males were more likely to die by suicide than females (Ivey-Stephenson et al., 2020).

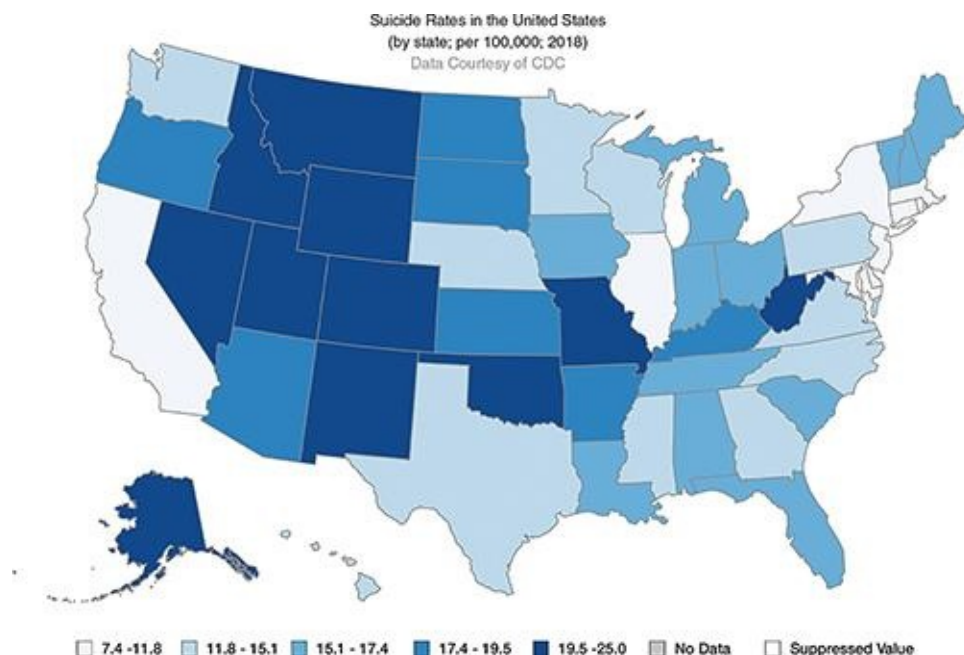

Figure 22-1: Number of deaths attributable to suicide in the United States per 100,000 population, 2018. Data courtesy of CDC. (Retrieved December 2020, from https://www.nimh.nih.gov/health/statistics/suicide.shtml#part_154973)

Adults and Older Adults

Suicide is a major contributor to premature death in adults, ranking the fourth leading cause of death among adults aged 35 to 54. Suicide rates peak during middle age, and a second peak occurs in those aged 75 years and older (Hedegaard et al., 2020; NIMH, 2020). Physical illness, pain, loss, loneliness, social isolation, and disconnectedness are important precipitants to suicide in older adults (Jones & Pastor, 2020; Schmutte & Wilkinson, 2020).

Suicide disproportionally affects those who have served in the military, with suicide rates for Veterans 1.5 times the rate for non-Veterans (U.S. Department of Veterans Affairs, 2019). An estimated 18 veterans die by suicide per day. Depression, Post Traumatic Stress Disorder (PTSD), and combat exposure are some of the leading contributing factors to suicide for both men and women military members (Nichter et al., 2020; Ursano et al., 2020). Other related factors include alcohol or substance dependence, intimate partner problems, legal/administrative stressors, and financial strain (Bryan & Bryan, 2019; Pruitt et al., 2019). For women, military sexual trauma also contributes to suicide ideational and attempts (Griffith, 2019).

Epidemiology and Risk Factors

Suicidal behavior is complex, and there can be many contributing factors. Mental illness is an important factor contributing to suicide in adults. Mood disorders, particularly recurrent depression, are associated with higher risk of suicide. Substance use disorder and personality disorders are also found to influence suicide risk in young adults (Gili et al., 2019). Auditory hallucinations increase the risk for suicide because of the possibility of individuals impulsively responding to “voices” directing them to hurt themselves. Substance abuse increases the likelihood that suicidal ideation will result in both parasuicidal and suicidal behaviors. [Box 22-2](#) identifies risk factors for suicide (CDC, 2020a, 2020b).

BOX 22.1

Suicide Risk Factors

Family history of suicide
Family history of child maltreatment
Previous suicide attempt(s)
History of mental disorders, particularly clinical depression
History of alcohol and substance abuse
Feelings of hopelessness
Impulsive or aggressive tendencies
Cultural and religious beliefs (e.g., belief that suicide is noble resolution of personal dilemma)
Local epidemics of suicide
Isolation, a feeling of being cut off from other people
Barriers to accessing mental health treatment
Loss (relational, social, work, or financial)
Physical illness
Easy access to lethal methods
Unwillingness to seek help because of the stigma attached to mental health and substance abuse disorders or to suicidal thoughts

Centers for Disease Control and Prevention, National Center for Injury Prevention and Control. (2020). Suicide risk and protective factors [Online].

<https://www.cdc.gov/violenceprevention/suicide/riskprotectivefactors.html>

Medical illness contributes to functional disability and also increases the likelihood of chronic depression, which, in turn, contributes to the increased suicide rate of those over the age of 65 (Nelson, 2019). Additionally, symptoms of comorbid illnesses often are similar to depressive disorder, making recognition of depressive disorder by primary care providers difficult. Patients are often reticent to disclose their suicidal thoughts, further complicating detection.

Psychological Risk Factors

Psychological pain, internal distress, low self-esteem, and interpersonal distress have long been associated with suicide (Ducasse et al., 2018). Childhood physical and sexual abuse is linked to suicide, suicide ideation, and parasuicide. Cognitive risk factors include problem-solving deficits, impulsivity, rumination, and hopelessness. Impulsivity, anger, and reduced inhibition increase the risk of suicide. Recent purchase of a handgun increases the risk of self-harm (CDC,

2020b; Crifasi et al., 2015; Wendell et al., 2016).

Social Risk Factors

Social isolation is a primary risk factor for suicide. Social distress leads to despair and can be caused by family discord, parental neglect, abuse, parental suicide, and divorce. Social distress can prevent the patient from accessing the support necessary to prevent suicidal acts. Other social factors associated with suicide risk include economic deprivation, unemployment, poverty, knowing someone who has died by suicide (especially if this person was a family member), and lack of access to behavioral health care (CDC, 2020b; Endo et al., 2017; Suicide Prevention Resource Center [SPRC], 2020a).

Gender

Males have a suicide completion rate nearly four times that of females. White males account for 70% of completed suicides, with middle-aged (ages 45 to 65 years) White men having the highest rate (AFSP, 2020). Men are more likely to use means that have a higher rate of success, with 56% of their suicide deaths by firearms (see [Fig. 22.2](#)). Men living in rural areas have a much higher risk of suicide than those in urban areas, and that gap is widening, perhaps attributable to the higher rates of gun ownership in rural areas (Logan et al., 2015). Substance abuse, aggression, hopelessness, emotion-focused coping, social isolation, and feeling little purpose in life have been associated with suicidal behavior in men.

Women across age, racial, and ethnic groups are less likely to die from suicide than are men but are more likely to attempt suicide. Women make three attempts to every attempt by men. Adolescent girls and women aged 10 to 44 years have the highest rate of suicide attempts. Women are less likely to complete a suicide, partly because they are more likely to choose less lethal methods. Women with current or previous exposure to domestic violence are at an increased risk for suicidal behavior (Kavak et al., 2018).

FIGURE 22-2: Suicide deaths by method in the United States (2018). Data courtesy of CDC. (Retrieved December 2020, from https://www.nimh.nih.gov/health/statistics/suicide.shtml#part_154971)

Sexuality

The lesbian, gay, bisexual, transgender, queer, questioning, and intersexed (LGBTQI) community is at increased risk for suicide (National Alliance on Mental Illness [NAMI], 2020). An estimated 1.8 million LGBTQI young people seriously consider suicide each year, with LGBTQI youth nearly five times as likely to attempt suicide compared with heterosexual youth (The Trevor Project, 2020). In lesbian, gay, and bisexual older adults, there are high levels of inadequate general health disability (Fredriksen-Goldsen et al., 2017).

Adolescents in sexual underrepresented groups are often stigmatized and discriminated against. They have more suicidal ideation, more suicide attempts, and are more at risk for completed suicides than their heterosexual peers (Yildiz, 2018). Individuals are more at risk for suicide when they experience conflict with family or friends because of their sexual identity, threat of violence, abuse, bullying, isolation, and other high risk behaviors (American Association of

Suicidology, 2019). A nationwide study of youth health behaviors and experiences reported a significantly higher percentage of lesbian, gay, or bisexual students (48%) seriously contemplated suicide, as compared with 13% of heterosexual students, and 23% of lesbian, gay, or bisexual students attempted suicide, as compared to 5% of heterosexual students (Kann et al., 2018).

There are alarming rates of suicide ideation and suicide rates among transgender individuals. In a national study, 40% of transgender adults reported a suicide attempt, with 92% of these individuals making their attempt before the age of 25 (James et al., 2016). Gender-based victimization, discrimination, bullying, violence, rejection by family, friends, and communities are risk factors associated with suicidal behavior (Testa et al., 2017; Virupaksha et al., 2016).

Race and Ethnicity

There is considerable variation in the profile of suicide rates across racial groups, including the age when rates are at their peak and the duration of high rates across several age groups. Rates of suicide among American Indian/Alaska Native people and White people are highest, at 22.1 and 18.0 per 100,000 respectively. Lower suicide rates are found among Asian/Pacific Island individuals (7.0 per 100,000), Hispanics (7.4 per 100,000), and Black (7.2 per 100,000) populations (SPRC, 2020b).

The rate of suicides among White people has steadily increased since 1999. Suicide rates are higher in males than in females in all age groups, with a rate of 22.8 (males) and 6.2 (females) per 100,000. Completed suicides are highest for White individuals between the ages of 35 and 64. Suicide rates among those older than 75 years are also high. The use of firearms is by far the most prominent method of suicide among White people (Hedegaard et al., 2020). Access to firearms contributes to the risk of completed suicides. Firearm ownership is more prevalent in the United States than in any other country, with an estimated 120 firearms per 100 people (Karp, 2018).

Suicide rates among American Indian and Alaska Native (AI/AN) populations are the highest of any racial/ ethnic group in the United States. Rates peak during adolescence and young adulthood, then decline (SPRC, 2020a). AI/AN populations engaged in suicidal behavior are more likely to have been exposed to suicide by a family member or friend and more likely to report substance use. For these reasons, community level prevention strategies focusing on survivor

support and substance use treatment are critical (Leavitt et al., 2018).

Family cohesion and social support in African American families contribute to the lower rates of suicide in this group. In 2018, the suicide rate among African American females was the lowest among men and women of all ethnicities. Although the overall suicide rate for African American individuals is low, young African American men take their lives at a rate considerably above that of other age groups. Higher rates of suicide in younger men may be associated with disparities in mental health treatment and social factors disproportionately affecting Black adolescents (Lindsey et al., 2019).

Even though the suicide rate for Hispanics is less than half of the overall US rate, in 2017 suicide was the second leading cause of death for Hispanics, aged 15 to 34. Among Hispanic populations, suicide rates remain somewhat consistent across the lifespan, and the death rate for Hispanic men is four times the rate of Hispanic women. Suicide attempts for Hispanic adolescents were 40% greater than non-Hispanic White adolescents (SPRC, 2020a; U.S. DHHS Office of Minority Health [OMH], 2020b).

While the suicide rate for Asian individuals or Pacific Island populations is approximately half of the overall suicide rate in the United States, the scant literature on suicide among Asian populations shows that suicide ideation, plans, and attempts may be more common than popularly believed and vary within Asian ethnic groups. In 2017, suicide was the leading cause of death for Asian American individuals aged 15 to 24. The suicide death rate for men is double that of women. Unlike that of the overall US population, in Asian or Pacific Islander populations, suicide rates peak later in life, in those over the age of 85 (SPRC, 2020a; U.S. DHHS OMH, 2020a). A study of racial/ethnic differences in youth having died by suicide found that Asian American/Pacific Islander youth had significantly lower rates of mental health treatment compared to White youth, consistent with research demonstrating disparities in mental health service utilization (Lee & Wong, 2020).

Pandemic Impact

While the full extent of the impact of coronavirus disease 2019 (COVID-19) on mental health will not be fully realized for quite some time, evidence of mental health challenges related to COVID-19-associated morbidity, mortality, and mitigation activities (including physical distancing and mandated stay-at-home

orders) were noted within months of the outbreak in the United States. A national survey of adults in June 2020 found that 41% of respondents reported at least one adverse mental or behavioral health condition related to COVID-19. Symptoms reported included anxiety or depression (31%), trauma/stress (26%), and having started or increased substance use (13%). Nearly 11% of respondents reported having seriously considered suicide in the previous month. In particular, younger adults, members of underrepresented racial/ethnic groups (Hispanic and Black persons), essential workers, and unpaid caregivers for adults were more likely to report disproportionately worse mental health outcomes, increased substance use, and increased suicidal ideation (Czeisler et al., 2020). Distress, anxiety, depression, fear of contagion, uncertainty, chronic stress, isolation, and economic hardship all contribute to a person being more vulnerable to negative impact (Sher, 2020).

Etiology

The convergence of biologic, psychological, and social factors can be directly linked to suicidal behavior. In genetically and physiologically vulnerable individuals, thoughts, feelings, and personality factors can interfere with personal problem-solving, promote impulsivity, and support suicidal behavior. Poverty, unemployment, and social conflict also contribute to suicidal behavior in those at risk for suicide. Figure 22.3 illustrates suicidal thoughts and behaviors among US adults.

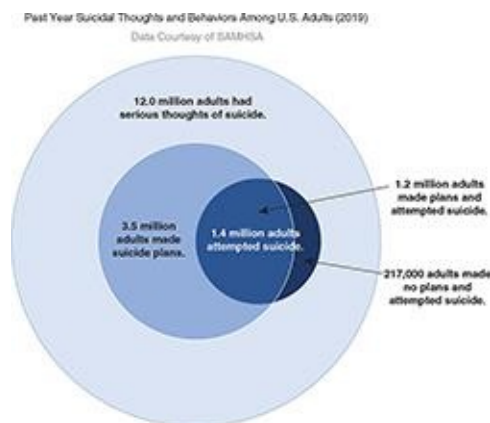

FIGURE 22-3: Past year suicidal thoughts and behaviors among U.S. adults (2019). Data courtesy of SAMHSA. (Retrieved December 2020, from

https://www.nimh.nih.gov/health/statistics/suicide.shtml#part_154973)

Biologic Theories

Depression and severe childhood trauma are linked to suicide. Those who complete suicide often have extremely low levels of the neurotransmitter serotonin. Impairments in the serotonergic system contribute to suicidal behavior. Additionally, dysregulation in the hypothalamic-pituitary-adrenal axis, abnormalities of neurotrophins and neurotrophin receptors, and abnormalities of neuroimmune functions may be associated with suicide risk (Orsolini et al., 2020).

Genetic Factors

Suicide runs in families. First-degree relatives of individuals who have completed suicide have a two to eight times higher risk for suicide than do individuals in the general population. Suicide of a first-degree relative is highly predictive of a serious attempt in another first-degree relative. Children of depressed and suicidal parents have higher rates of suicidal behavior themselves. The genetic link to suicide is evident in twin studies. Suicidal behavior has a 50% concordance for completed suicide (Tidemalm et al., 2011).

There also appears to be a gene/environment connection between early childhood sexual abuse and suicidality. Early childhood adverse experiences appear to lead to genetic changes that modify the expression of the neurologic system, impacting the biologic and psychological development. As a result, there is a propensity to react to stressors, increasing the likelihood of suicidal behavior (Brodsky, 2016).

Psychological Theories

Cognitive Theories

Most evidences on the psychological contributions to suicidal behavior point to cognitive, affective, behavioral, and personality factors that intensify the

experience of hopelessness and disconnection from others. Aaron Beck first identified the cognitive triad of hopelessness, helplessness, and worthlessness as integral to the experience of depression (Beck et al., 1979). Since then, a significant evidence base has been established linking hopelessness, loneliness, and other cognitive symptoms to suicide ideation (Klonsky et al., 2017). Depressed persons who are hopeless are more likely to consider suicide than those who are depressed but hopeful about the future. Furthermore, it appears that lack of positive thoughts about the future is more likely to predict suicidal behavior than negative thoughts even though both contribute to hopelessness (Liu et al., 2017).

KEYCONCEPT **Hopelessness** is the pervasive belief that undesirable events are likely to occur, coupled with the belief that one's situation is unlikely to improve (Ellis & Rutherford, 2008).

Emotional and Personality Factors

Emotional factors and personality traits also play a role in suicidal behavior by enhancing perceptions of helplessness and hopelessness, contributing to poor self-esteem, and interfering with coping efforts. Shame, guilt, despair, and emotion-focused coping have been linked to suicidal behavior. Loss and grief are also important considerations. Emotional distress often is potentiated by personality traits that contribute to poor self-esteem, impulsivity, and suicidal behavior (Rutter et al., 2020).

Ideation to Action Theories

Suicide ideation does not necessarily lead to suicide attempts. Most people who think of suicide do not act on the idea, but the suicide thoughts of those who do take lethal actions are often indistinguishable from those who do not (see [Figure 22.3](#)). Ideation-to-action theories examine factors that identify those who are most likely to attempt suicide. These emerging theories, which are supported by research, provide a basis for discriminating between those who are only thinking about suicide versus those who are likely to engage in suicidal acts.

The *Interpersonal Psychological Theory of Suicidal Behavior (IPTs)*, introduced by Thomas Joiner in 2005, proposes that three interacting factors indicate a high risk of suicide—"thwarted belongingness", perceived burdensomeness, and acquired capability. The term *thwarted belongingness* is

used to describe alienation from social relationships or experiences; the human need to belong is not being met. It refers to an individual's feelings of loneliness and isolation, as well as a lack of reciprocal, caring, and meaningful relationships. Perceived burdensomeness is the perception that the individual is a burden to others. **Acquired capability for suicide**, which develops over time, involves a heightened sense of fearlessness and a high pain threshold (Joiner, 2005).

IPTS views the act of suicide as being very difficult to carry out. When thwarted belongingness, perceived burdensomeness, and acquired capability come together in one person, these beliefs lead to the misperception that others would be better off without them and the idea that sacrificing themselves is the appropriate action to take. Researchers are testing the theory in a variety of clinical situations (Kang et al., 2019; Ma et al., 2016, 2019).

Integrated Motivational Volitional model proposes that motivational factors, such as defeat and entrapment, cause suicide ideation. The progression from suicide ideation to suicide attempt is explained by **volitional factors**, such as acquired capability, access to lethal means, planning, and impulsivity (O'Connor & Kirtley, 2018). In a study differentiating between those thinking about suicide and those attempting suicide, those reporting a suicide attempt were found to have greater acquired capability, mental imagery about death, and impulsivity, and were more likely to know a friend who had made a previous attempt (Wetherall et al., 2018).

The *Three-Step Theory (3ST)* explains progression from ideation to action in three steps. First, emotional pain and hopelessness cause the suicide ideation. Second, thoughts of suicide become strong as the emotional pain exceeds connectedness. The third step involves the actual attempt when the person has the knowledge and capacity to carry out the suicide (Klonsky et al., 2017). In this model, suicide prevention focuses on reducing pain, increasing hope, improving connections, and reducing capacity to carry out the suicide.

Social Theories

Before the turn of the 20th century, Emile Durkheim (1951[1897]) linked suicide to the social conditions in which people live. Both a lack of social connectedness and social conditions contribute to suicidal behavior. People who are socially connected are less likely to engage in suicidal behavior. When an individual has

others they can depend on, suicide can be prevented, even among those at significant risk. Even among people with social bonds, however, lack of community and social resources can interact with physiologic and psychological risk to increase the likelihood of suicide.

Social Distress

A lack of social connection contributes to suicide ideation, attempts, and deaths across the age span. Among adults, those who are single, never married, separated, widowed, living alone, and those reporting loneliness, alienation, and a lack of belongingness, are also more likely to engage in suicidal behavior (Calati et al., 2019). Being socially connected, however, does not in itself reduce risk. Interpersonal conflict, sexual underrepresented groups, and being a victim of bullying can contribute to suicidal behavior, especially in adolescents and young adults (John et al., 2018).

Suicide Contagion

Social exposure to suicide is associated with an increased personal risk for suicidal behavior, particularly among adolescents. Suicidal behavior that occurs after the suicide death of a known other is called suicide contagion or cluster suicide. **Suicide contagion** seems to work through modeling and is more likely to occur when the individual contemplating suicide is of the same age, gender, and background as the person who died. Contagion can be prompted by the suicide of a friend, an acquaintance, online social networking, or an idolized celebrity. Actions of peer groups, media reports of suicide, and even billboards with content about suicide can trigger suicide behavior among adolescents. In the case of a celebrity suicide, the number of “copycat suicides” is proportional to the amount, duration, and prominence of media coverage (Colman, 2018). Evidence suggests that adolescents can also be influenced by simple individual and community suicide prevention efforts (Zimmerman et al., 2016).

Economic Disadvantage

Poverty and economic disadvantage are associated with depression, suicide ideation, and suicide mortality. Individuals who are not employed, not married, and with low education and low income have a higher risk of suicide. Suicide

risk is greater for adults in socially and materially deprived areas (Kerr et al., 2017). Adolescents from impoverished neighborhoods have more suicidal ideation and attempts, and suicides increase as the percentage of boarded-up buildings in a neighborhood increases, particularly if the individuals have a mental disorder (Page et al., 2014).

In impoverished communities, particularly rural America, lack of good schools and employment opportunities leads to unemployment and loss of meaningful social roles. Access to health care is limited in these communities, and there is an increased exposure to others exhibiting suicidal behavior that enhances suicide risk (Carpenter-Song & Snell-Rood, 2017).

Family Response to Suicide

Suicide has devastating effects on everyone it touches, especially family and close friends. One suicide is estimated to leave at least six survivors who are significantly impacted by the loss (Andriessen et al., 2016). In the aftermath of a family member's suicide, survivors experience more grief, anxiety and depression, guilt, shame, self-blame, and dysfunction than families whose loss was because of other reasons and the personal and familial disruption often lasts for years. Although recovery from a loved one's suicide is an ongoing task, survivors who are emotionally healthy before the suicide act and who have social support are able to manage the psychological trauma associated with suicide. Still, the intensity and duration of the postsuicide grief process for many survivors has led to the development of family intervention programs. Although the evidence base for these interventions is still small, strategies that support a positive sense of self, enhance problem-solving, promote the formation of a suicide story, encourage social reintegration, reduce stigma, use journaling, or permit the survivor to debrief may be effective in reducing subjective distress and to resolve grief (Andriessen et al., 2016). These strategies may be most effectively delivered in survivor peer help groups.

Protective Factors

Protective factors buffer individuals from suicidal thoughts and behavior.

Although identifying and understanding protective factors is very important, they have not been studied as extensively as risk factors. The Centers for Disease Control and Prevention identifies the following protective factors (CDC, 2020b).

- Effective clinical care for mental, physical, and substance abuse disorders
- Easy access to a variety of clinical interventions and support for help seeking
- Family and community support (connectedness)
- Support from ongoing medical and mental health care relationships
- Skills in problem-solving, conflict resolution, and nonviolent ways of handling disputes
- Cultural and religious beliefs that discourage suicide and support instincts for self-preservation

TREATMENT AND NURSING CARE FOR SUICIDE PREVENTION

Interdisciplinary Treatment and Recovery

The challenges of preventing suicides and promoting healthy coping belong to all disciplines. An interdisciplinary treatment or recovery approach along with peer support is needed for managing the threats of suicide.

Clinical Judgment

Concept Mastery Alert

A true psychiatric emergency exists when an individual presents with one or more symptoms associated with imminent risk for suicidal behavior. Immediate and focused action is needed to prevent the patient's death.

The first priority is to provide for the patient's safety while initiating the *least* restrictive care possible. In contrast, an example of the *most* restrictive care is an outpatient who is admitted to a locked unit with one staff member who is assigned to observe the person at all times. Hospitalization should be reserved

for those whose safety cannot be ensured in an outpatient environment.

Priority Care Issues: Preventing Suicide and Promoting Mental Health

Suicidal ideation, planning, and acts are not easily predicted and, therefore, are difficult to study. As a result, few evidence-based treatments exist that are known to prevent suicide and manage suicidal behavior. There is growing consensus that the suicidal act is part of a continuum of behaviors that extend long before and after a specific suicide behavioral incident. The beginning evidence points to four steps in preventing suicide and promoting long-term mental health: identification of those thinking about suicide (case finding), assessment to determine an imminent suicidal threat, intervening to change suicidal behavior associated with a specific suicidal threat, and institution of effective interventions to prevent future episodes of suicidal behavior.

Assessment

Case Finding

Case finding refers to identifying people who are at risk for suicide so proper treatment can be initiated. People who are contemplating suicide often do not share their ideation. This lack of disclosure often means that family, friends, and health professionals are unable to intervene until the suicidal ideation and planning have progressed. Yet early identification of suicidal ideation may reduce suicide deaths. Nurses can play important roles in suicide prevention by recognizing the warning signs. See [Box 22.3](#) for the warning signs developed by the American Association of Suicidology (2020); the mnemonic IS PATH WARM can serve as a useful memory aide for these signs. The Columbia Suicide Severity Rating Scale (C-SSRS) is a commonly used evidence-supported suicide risk assessment that measures severity of suicidal ideation, intensity of ideation, suicidal behavior, and lethality (See [Chapter 11](#) for more information about the C-SSRS).

BOX 22.3

Warning Signs for Suicide

- I—Ideation: Talking or writing about death, dying, or suicide
 - Threatening or talking of wanting to hurt or kill self
 - Looking for ways to kill self: seeking access to firearms, available pills, or other means
- S—Substance abuse: Increased substance (alcohol or drug) use
- P—Purposelessness: No perceived reason for living; no sense of purpose in life
- A—Anxiety: Anxiety, agitation, unable to sleep, or sleeping all the time
- T—Trapped: Feeling trapped (like there is no way out)
- H—Hopelessness
- W—Withdrawal: Withdrawal from friends, family, and society
- A—Anger: Rage, uncontrolled anger, seeking revenge
- R—Recklessness: Acting reckless or engaging in risky activities, seemingly without thinking
- M—Mood change: Dramatic mood changes

Adapted from American Association of Suicidology. (2020). Know the warning signs.

<https://suicidology.org/resources/warning-signs/>

Case finding requires careful and concerned questioning and listening that make the patient feel valued and cared about (Box 22.4>). Most standardized health questionnaires have questions about suicide thoughts. Many nurses are concerned that asking patients about their suicidal thoughts will provoke a suicide attempt. This belief simply is not true. The patient expressing suicidal ideation often has had these thoughts for some time and may feel more socially connected when another recognizes the seriousness of the situation. Under no circumstances should a patient be promised secrecy about suicidal thoughts, plans, or acts. Instead, tell patients that disclosure of suicidal intent will be shared with other interdisciplinary team members so the safety of the patient can be ensured.

BOX 22.4 • THERAPEUTIC DIALOGUE

Suicide

When Caroline sought medical care for a cold from her nurse practitioner, the nurse observed more than a cough and runny nose. Caroline appeared downcast and unusually sad. As the nurse and patient talked, the subject of family life came up, whereupon Caroline began to cry softly. As words tumbled out, she said she had been unhappy at home for a long time. When she was very young, she recalled being happy, but things changed when her brother was born, 4 years after her. Her father began to abuse her sexually, starting when Caroline was 5 years old and continuing until he moved out of the house when she was 12 years old. Caroline suspects her mother knew of the abuse, although she did nothing about it.

Two years ago, Caroline's father committed suicide. Caroline feels relieved about his death but frustrated

that she never got a chance to tell him how angry she was with him. Caroline's relationship with her mother has not improved. Caroline says her mother favors her brother and is always telling her she won't amount to anything. Caroline begins to cry harder.

Ineffective Approach

Nurse: Clearly, many things are troubling you. Don't you think that things seem worse now because you have a cold?

Caroline: Well, that could be. What are you going to do to make me feel better?

Nurse: Give you some medicine to help you sleep and clear your nose. I think you should see a psychiatrist, too.

Caroline: I don't need a psychiatrist. I came here for my cold.

Nurse: I know you did, but you seem to be depressed.

Caroline: What are you, some kind of social worker? I am just tired.

Nurse: I am a nurse, and you seem down to me. Are you thinking about suicide?

Caroline: I don't think you know what you're talking about. I want to go now. Could you give me my medicine?

Effective Approach

Nurse: It seems as though many things have been piling up on you. Does it seem that way to you, too?

Caroline: It sure does. I've just been trying to get through 1 day at a time, but now with this cold and no sleep, I feel like I can't go on.

Nurse: When you say you can't go on, what does that mean to you?

Caroline: Lately, I have been thinking about running away to some place where I can't be found and maybe starting over. But then I think, where would I go? Where would I stay? Who would take care of me?

Nurse: When you think that your plan for escape won't work, what happens?

Caroline: (Starting to cry again.) Then I think that maybe it would be better if I just did what my father did. I really don't think anyone would miss me.

Nurse: So you think you might take your life, like your Dad did?

Caroline: Yeah, and what really scares me is lately I have been thinking about that a lot. I keep saying to myself, "You're just tired," but I am so exhausted now that I can't chase the thoughts away.

Nurse: So, do you think about suicide every day?

Caroline: It seems like I never stop thinking about it.

Nurse: Is there anything you can do to make the thoughts go away?

Caroline: Nothing. (Silence.)

Nurse: What would you do?

Critical Thinking Challenge

In the first interaction, the nurse made two key blunders.

- What were they?
- What effect did they have on the patient?
- How did they interfere with the patient's care?

Assessing Risk

After suicidal ideation has been established, the next step is to determine the risk for a suicide attempt. Suicide risk assessment is difficult and whenever possible should proceed only with the assistance of other members of the interdisciplinary treatment team. Assessing for risk includes determining the seriousness of the suicidal ideation, degree of hopelessness, disorders, previous attempt, suicide planning and implementation, and availability and lethality of suicide method. Risk assessment also includes the patient's resources, including coping skills and social supports, that can be used to counter suicidal impulses. [Box 22.5](#)> lists some questions that might be asked in assessing the risk for suicide.

The greatest predictor of a future suicide attempt is a previous attempt, partly because the individual already has broken the “taboo” around suicidal behavior. Repeated episodes of self-harm with or without suicidal intent also increase immediate risk because they increase an individual's capacity to complete suicide. Other important signs of high risk are the presence of suicide planning behaviors (detailed plan, availability of means, opportunity, and capability) and engaging in final acts, such as giving away prized possessions and saying goodbye to loved ones. Although the presence of a specific psychiatric disorder, such as depression, is an important consideration in risk assessment, anxiety, agitation, alcohol use, and impulsivity may be better indicators of immediate risk. However, support from important others, religious prohibitions, responsibility for young children, and employment may provide protection from suicidal impulses.

BOX 22.5

Assessment of Suicidal Episode

INTENT TO DIE

1. Have you been thinking about hurting or killing yourself?
2. How seriously do you want to die?
3. Have you attempted suicide before?
4. Are there people or things in your life who might keep you from killing yourself?

SEVERITY OF IDEATION

1. How often do you have these thoughts?
2. How long do they last?
3. How much do the thoughts distress you?
4. Can you dismiss them or do they tend to return?
5. Are they increasing in intensity and frequency?

Degree of Planning

1. Have you made any plans to kill yourself? If yes, what are they?
2. Do you have access to the materials (e.g., gun, poison, pills) that you plan to use to kill yourself?
3. How likely is it that you could actually carry out the plan?
4. Have you done anything to put the plan into action?
5. Could you stop yourself from killing yourself?

Ideally, an interdisciplinary team conducts suicide risk assessment in an emergency department or outpatient facility with multiple supports. Nurses practicing in more isolated situations should keep a list of contacts in settings that routinely conduct suicide risk assessments so the contacts may be consulted if a seriously suicidal individual appears in the nurse's setting.

NCLEXNOTE Suicide assessment is always considered a priority. Practice by asking patients about suicidal thoughts and plans. Develop a plan with a suicidal patient that focuses on resisting the suicidal impulse. Apply the assessment process that delineates the (1) intent to die, (2) severity of ideation, (3) availability of means, and (4) degree of planning.

Interventions for Imminent, Intermediate, and Long-Term Suicide Prevention

Interventions for Those at Imminent Risk

There are three urgent priorities for care of a person who is at imminent risk for suicide: reconnecting the patient to other people and instilling hope, restoring

emotional stability, and reducing suicidal behavior, and ensuring safety. Reconnecting the patient interpersonally includes listening intently, and without judgment, to the patient's thoughts and feelings and validating their experience and suffering. This intervention directly challenges the patient's belief that no one cares. Using cognitive interventions can help the client regain hope and establish goals for the future (see [Chapter 13](#)).

Ensuring Patient Safety

Helping patients develop strategies for making safer choices when distressed is an important goal. Nurses caring for patients who are emerging from the initial hours and days of a suicide attempt can support the patient and focus on managing suicidal urges and developing protective strategies. As the nurse connects with the patient, together they can create a list of personal and professional resources that can be used when the individual is in crisis. With the nurse's help, the patient can visualize "emotional spaces that are safe places to go" when distressed.

For years, the no-suicide contract was a staple of psychiatric nursing practice and widely used across disciplines as a means of preventing suicide among those at risk. No-suicide contracts are verbal and written "contracts" between the individual at imminent risk for suicide and a health care provider that contain an agreement that the patient will not commit suicide during a specific time period. Careful evaluation of this practice has not established its efficacy in preventing suicidal behavior and suicide deaths. As a consequence, the nurse should avoid engaging in a no-suicide contract with a patient (Matarazzo et al., 2014).

Inpatient Safety Considerations

When hospitalization is considered the best option to ensure the safety of the patient, the nurse has responsibility for providing a safe, therapeutic environment in which human connection, instilling hope, and changing suicidal behavior can occur. There are no evidence-based guidelines for preventing suicides in hospitals. Inpatient suicides do occur. One study reported an average of 50 to 65 hospital inpatient suicides occurring per year in the United States. The vast majority of inpatient suicides take place in psychiatric facilities, and the method used in 70% of these events is hanging (Williams et al., 2018).

Removal of dangerous items and environmental hazards, continuous or

intermittent observation of at-risk patients by hospital personnel trained in observation methods, and limitation of outpatient passes are the mainstays of hospital interventions. Observation procedures vary from facility to facility. For patients who require constant supervision, a staff member will be assigned only to the high-risk patient. For less risky patients, observation may entail close or intermittent observations.

Observation is not, in itself, therapeutic. An observation becomes therapeutic when interaction occurs with the patient. Psychiatric intensive care of this kind and restriction of freedom can be very upsetting to the patient who is withdrawn and isolated. Nurses can help patients reestablish personal control by including them in decisions about their care and restricting their behavior only as necessary. Nurses can also reduce the patient's stress while ensuring the patient's safety by intruding as little as possible on the person's exercise of free will. Observational periods can be used to help patients express a broad range of feelings and strengthen their belief in their own abilities to keep themselves safe. During observation, the nurse can help the patient describe feelings and identify ways to manage safety needs ([Box 22.6](#)).

BOX 22.6

Suicide Prevention

When teaching the patient and family about suicide and its prevention, be sure to address the following topics:

- Importance of emotional connections to family and friends
- Importance of instilling hope
- Discouraging suicidal ideation, rumination, self-harming behaviors
- Self-validation
- Emotional distress management
- Finding alternatives to suicidal behavior
- Establishing and using a crisis management plan
- Reestablishing the social network of the patient
- Information about treatment of underlying psychiatric disorders

Interventions for Intermediate and Long-Term Risk

Patients who are suicidal may need ongoing preventive interventions. The risk varies with the genetic, psychiatric, and psychological profile of the patient and the extent of their social support. Discouragement and hopelessness often persist long past the suicidal episode. Episodes of hopelessness should be anticipated

and planned for in the patient's care. Patients should be taught to expect setbacks and times when they are unable to see much of a future for themselves. They should be encouraged to think of times in their lives when they were not so hopeless and consider how they may feel similarly in the future. Helping patients review the goals they already have achieved and at the same time set goals that can be achieved in the immediate future can help them manage periods of discouragement and hopelessness.

Interventions for the Biologic Domain

Patients who have survived a suicide attempt often need physical care of their self-inflicted injury. Overdose, gunshot wounds, and skin wounds are common. There will be biologic interventions for the underlying psychiatric disorder (see Unit VI).

Medication Management

Medication management focuses on treating the underlying psychiatric disorder. Currently, clozapine is the only U.S. Food and Drug Administration–approved medication for suicide risk in individuals with schizophrenia. Studies showing reduced suicide risk in patients with bipolar disorder or major depression taking lithium are not conclusive. For depression, a nonlethal antidepressant, such as a selective serotonin reuptake inhibitor, usually will be prescribed (AFSP, 2020b).

Electroconvulsive Therapy

Electroconvulsive therapy (ECT) has been used in both inpatient and outpatient settings to alleviate severe depression, especially in medically compromised groups, such as older adults, who may not tolerate conventional pharmacotherapy for depression (see [Chapter 12](#)). Rapid reduction in depression often leads to a decreased suicide drive. More research is needed to determine the role ECT may play in managing suicidal behavior. At this time, ECT is among several strategies used to decrease suicidal behavior over the long term (AFSP, 2020b; Kellner & Patel, 2018).

Interventions for the Psychological Domain

The goals of treatment in the psychological domain include reducing the capacity for suicidal behavior, increasing tolerance for distress, expanding coping abilities, and developing effective crisis management strategies. During the early part of a hospitalization, the most important way to reduce stress is to help the patient feel more secure and hopeful. As patients become more comfortable in their environment, the nurse can provide education about emotions, help patients explore and link presuicidal beliefs to a positive and hopeful future, support the application of new skills in managing negative thoughts, and help develop effective problem-solving skills.

Challenging the Suicidal Mindset

Teaching patients to distract themselves when thinking about suicide or engaging in negative self-evaluation can help to diminish suicidal ideation, dysfunctional thinking, and emotional reactivity. Simple distracting techniques such as reminding oneself to think of other things or engaging in other activities such as talking on the telephone, reading, or watching a movie are excellent temporary means of distracting the patient from negative cognitive states (see [Box 22.6](#)>).

Validating the patient and teaching the patient to self-validate are powerful means of reducing suicidal thinking. Patients can learn that everyone experiences emotional distress and can begin to recognize it as a routine event. To manage emotional distress and increase tolerance for it, patients can be taught simple anxiety management strategies such as relaxation and visualization. The patient can be encouraged to write about their emotional experiences.

When negative thoughts and emotions coexist, they reinforce each other and contribute to suicidal ideation. Individuals who are suicidal often believe they are a burden to their family, who would be better off without them and do not feel connected to others. Nurses can challenge negative beliefs, especially the patient's idea that they are a burden to others (see [Chapter 13](#)). Ask the patient to describe the events that led to specific suicidal behavior so the patient can be engaged in developing alternative solutions. For each event, work with the patient to identify specific strategies that could be used to manage their distress, sense of disconnection, extreme focus on suicidal ideas, and other experiences that led the person to believe they had no option other than to die.

Developing New Coping Strategies

Preventing suicidal behavior requires that patients develop crisis management strategies, generate solutions to difficult life circumstances other than suicide, engage in effective interpersonal interactions, and maintain hope. The nurse can help the patient develop a written plan that can be used as a blueprint for action when the patient feels that they are losing control. The plan should include strategies that the patient can use to self-soothe; friends and family members that could be called, including multiple phone numbers where they can be reached; self-help groups and services such as suicide hotlines; and professional resources, including emergency departments and outpatient emergency psychiatric services.

Commitment to Treatment

Patients are usually ambivalent about wanting to die. **The commitment to treatment statement (CTS)** directly addresses ambivalence about treatment by asking the patient to engage in treatment by making a commitment to try new approaches. Different from the no-suicide contract, the CTS does not restrict the patient's rights regarding the option of suicide. Instead, the patient agrees to engage in treatment and access emergency service if needed. Underlying the CTS is the expectation that the patient will communicate openly and honestly about all aspects of treatment, including suicide. This commitment is written and signed by the patient. The efficacy of this approach has yet to be established by systematic research. Whether using the CTS or other means, be observant for lapses in the patient's participation in treatment and discuss them with the patient and other members of the interdisciplinary team.

Interventions for the Social Domain

Poor social skills may interfere with the patient's ability to engage others. The nurse should assess the patient's social capability early in treatment and make necessary provisions for social skills training. The interpersonal relationship with the nurse is an ideal place to begin shaping social behaviors that will help the patient to establish a social network that will sustain them during periods of discouragement or crisis. Participation in support networks, such as recovery

groups, clubhouses, drop-in centers, self-help groups, or other therapeutic social engagement, will help the patient become connected to others.

Patients need to anticipate that even some of the people closest to them will feel uncomfortable with their suicidal behavior. Helping the patient to anticipate the stigmatizing behavior of others and how to manage it will go far in reintegrating the patient into a supportive social community. The nurse can also explore the patient's participation in specific social activities such as attending church or community activities.

Evaluation and Treatment Outcomes

The most desirable treatment outcome is the patient's recovery with no future suicide attempts. Short-term outcomes include maintaining the patient's safety, averting suicide, and mobilizing the patient's resources. Whether the patient is hospitalized or cared for in the community, their emotional distress must be reduced. Long-term outcomes must focus on maintaining the patient in psychiatric treatment, enabling the patient and family to identify and manage suicidal crises effectively, and widening the patient's support network.

Continuum of Care

Whether the suicide prevention plan is instituted in the hospital or in an outpatient setting, the patient cannot be released to home until a workable plan of care is in place. The care plan includes scheduling an appointment for outpatient treatment, providing for continuing somatic treatments until the first outpatient treatment visit, ensuring postrelease contact between the patient and significant other, providing for access to emergency psychiatric care, and arranging the patient's environment so it provides both structure and safety.

At the first follow-up visit, the patient and health care provider can establish a plan of care that specifies the intensity of outpatient care. Very unstable patients may need frequent supervision (e.g., telephone or face-to-face meetings or both) in the early days after hospitalization to maintain the patient's safety in the community. These contacts often can be short; their purpose is to convey the ongoing concern and caring of professionals involved in the patient's care. In arranging outpatient care, be certain to refer the patient to a provider who can

provide the intensity of care the patient may need.

The patient's outpatient environment should be made as safe as possible before discharge. The nurse must share the care plan with family members so they can remove any objects in the patient's environment that could be used to engage in self-harm. The nurse should explain this measure to the patient to reinforce their sense of self-control. It is important to be reasonable in deciding what to remove from the environment. Patients who are truly determined to kill themselves after discharge will succeed in doing so, using whatever means are available.

Documentation and Reporting

The nurse must thoroughly document encounters with patients who are suicidal. This action is for the patient's ongoing treatment and the nurse's protection. Lawsuits for malpractice in psychiatric settings often involve completed suicides. The medical record must reflect that the nurse took every reasonable action to provide for the patient's safety.

The record should describe the patient's history, assessment, and interventions agreed upon by the patient and nurse. The nurse should document the presence or absence of suicidal thoughts, intent, plan, and available means to illustrate the patient's current and ongoing suicide risk. If the patient denies any suicidal ideation, it is important that the denial is documented. Documentation must include any use of drugs, alcohol, or prescription medications by the patient during 6 hours before the assessment. It should include the use of antidepressants that are especially lethal (e.g., tricyclics), as well as any medication that might impair the patient's judgment (e.g., a sleep medication). Notes should reflect the level of the patient's judgment and ability to be a partner in treatment.

The documentation should reflect if any medications were prescribed, the dosages, and the number of pills dispensed. Notes should reflect the plan for ongoing treatment, including the time of the next appointment with the provider, instructions given to the patient about obtaining emergency care if needed, and the names of family members and friends who will act as supports if the patient needs them.

NURSES' REFLECTION

Caring for suicidal patients is highly stressful and can lead to secondary trauma for the nurse. Nurses who care for suicidal patients must regularly share their experiences and feelings with one another. Talking about how the situations or actions of patients make them feel will help alleviate symptoms of stress. Some nurses find outpatient therapy helpful because it enhances their understanding of what situations are most likely to trigger secondary trauma. By demonstrating how to effectively manage the stressors in their own lives, nurses can be powerful role models for their patients.

SUMMARY OF KEY POINTS

- Suicide is a common and major public health problem.
- Suicide completion is more common in White men, especially older men.
- Parasuicide is more common among women than men.
- People who attempt suicide and fail are likely to try again without treatment.
- Suicidal behavior has genetic, biologic, and psychosocial origins.
- Suicide is associated with feelings of being a burden and not belonging.
- Acquired capability for suicide means that the person is fearless about death and has a high pain threshold.
- A suicide assessment focuses on the intention to die, hopelessness, available means, previous attempts and self-harm behavior, and degree of planning.
- Patients who are in crisis, are depressed, or use substances are at risk for suicide.
- The major objectives of brief hospital care are to maintain the patient's safety, reestablish the patient's biologic equilibrium, help the patient reconnect to others, instill hope, strengthen the patient's cognitive coping skills, and develop an outpatient support system.
- The nurse who cares for suicidal patients is vulnerable to secondary trauma

and must take steps to maintain personal mental health.

CRITICAL THINKING CHALLENGES

1. An African American woman who lives with her three children, husband, and mother comes to her primary care provider. She is tearful and very depressed. What factors should be investigated to determine her risk for suicide and need for hospitalization?
2. A woman experiencing poverty with no insurance is hospitalized after her third suicide attempt. Antidepressant medication is prescribed. What kinds of treatment will be most effective in preventing future suicidal behavior?
3. A young man enters his workplace inebriated and carrying a gun. He does not threaten anyone but says that he must end it all. Assuming that he can be disarmed, what civil rights must be considered in taking further action in managing his suicidal risk?
4. You are a nurse in a large outpatient primary care setting responsible for an impoverished population. You want to implement a case-finding program for suicide prevention. Discuss how you would proceed and some potential problems you might face.

Movie Viewing Guides

Daughter of a Suicide: 1996 (Documentary). This personal documentary is the story of a woman whose mother committed suicide when the daughter was 18 years old. The daughter recounts the emotional struggle and depression left as the lifelong legacy of suicide and explores her efforts to heal. Combining digital video, 16-mm, and super-8 film, *Daughter of a Suicide* uses interviews with family and friends to tell the story of both mother and daughter.

VIEWING POINTS: How does this movie show that the effects of suicide do not end with a person's death?

The Virgin Suicides: 1999. After the suicide death of their 13-year-old daughter Cecilia, the Lisbon family becomes recluses. The remaining daughters try to resume their life by defying the withdrawal of their parents. Unsuccessful, the movie climaxes with the suicide deaths of the three remaining teenage girls.

VIEWING POINTS: What conditions in the girls' family led the girls to take

their lives?

Paradise Now: 2005. This movie traces the motivations of two suicide bombers in Palestine. It explores how the two young men came to the decision to kill themselves and others and their ambivalence about their impending deaths. Ultimately, one decides to live, and the movie ends with an ambiguous fate of the other. This movie provides insight into the background and troubled thoughts that precede a suicidal act.

VIEWING POINTS: Can suicide be a political act? What other factors in these young men's lives might have contributed to their decision to volunteer as suicide bombers?

Mental Health Care for Survivors of Violence

Beverly Baliko

KEYCONCEPTS

- intimate partner violence
- psychological abuse
- sexual assault

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Describe types of violence and abuse, including intimate partner violence, stalking, rape and sexual assault, child abuse and neglect, and elder abuse.
2. Describe selected theories of violence.
3. Compare the reasons some people become abusive and why some victims remain in violent relationships.
4. Discuss the formation of a therapeutic relationship with a victim of violence.
5. Formulate nursing care plans for survivors of violence and abuse.
6. Describe treatment for perpetrators of abuse.

KEY TERMS

- Child abuse
- Child neglect
- Cycle of violence
- Elder abuse
- Intergenerational transmission of violence
- Rape
- Revictimization
- Stalking

INTRODUCTION

Violence in the form of abuse of intimate partners, children, and older adults is a national health problem. This type of violence permanently changes the survivor's reality and meaning of life. It wounds deeply, endangering core beliefs about the self, others, and the world. It can damage or destroy the survivor's self-esteem.

Nurses encounter survivors of violence and abuse in all health care settings. For this reason, being knowledgeable about abuse risk factors, indicators, causes, assessment techniques, and effective nursing interventions is a must. This chapter presents evidence that can shape contemporary nursing practice in caring for persons and families who survive violence and abuse.

TYPES OF VIOLENCE AND ABUSE

The most common type of abuse occurs as a result of domestic (family) violence; that is, the perpetrator is or formerly was a loved and trusted partner or family member. When this kind of violence occurs, the world and home are no longer safe in the eyes of the survivor. This chapter includes a discussion of intimate partner violence (IPV), **child abuse** and neglect, and **elder abuse** with emphasis on IPV.

Intimate Partner Violence

IPV is a significant public health problem in the United States, and across the globe. Behaviors that constitute IPV include physical, sexual, and psychological (emotional) abuse or a combination of these perpetrated by a current or former spouse, significant other, or dating partner. The prevalence of IPV can only be estimated, because much abuse goes unreported. The most recent data available suggest that during their lifetimes, 1 in 4 women and nearly 1 in 10 men experience adverse psychological or physical consequences related to physical or sexual violence perpetrated by an intimate partner (Smith et al., 2018). Economic costs associated with acute and chronic medical and mental health services for survivors, lost productivity, and criminal justice activities create a substantial ongoing societal burden (Peterson et al., 2018). Approximately 62% of female murder victims are killed by current or former intimate partners (Violence Policy Center, 2019).

KEYCONCEPT **intimate partner violence** involves physical violence, sexual violence, stalking, and psychological aggression (including coercive acts) by a current or former intimate partner. IPV occurs on a continuum from psychological abuse to lethal violence.

Physical Abuse

Physical abuse involves any act of aggression, with or without use of an object or a weapon, that results in injury, pain, or impairment to another. Examples include striking, kicking, shoving, choking, and burning. Frequently, this

behavior becomes a pattern that increases in severity over time. Physical abuse not only causes immediate injuries but also contributes to health problems that may persist long after the abuse ends. Although anyone can be a victim or perpetrator of physical abuse, women are far more likely than men to be seriously injured or killed by an intimate partner.

Psychological Abuse

KEYCONCEPT Psychological abuse (also referred to as emotional abuse) involves threats, intimidation, or violence used as a means of asserting dominance and causing fear. Psychological abuse includes behaviors such as criticizing, insulting, humiliating, or ridiculing someone in private or in public. Abusers may destroy property, threaten or harm pets, control or monitor spending and daily activities, or isolate a person from family and friends. Gaslighting is a form of psychological abuse in which the victim is made to question his or her own judgment and perceptions. Perpetrators downplay the consequences of their behavior, deny abusive intent, or argue that actions are somehow justified. They often blame the victim for provoking or otherwise causing the abuse, leaving the victim with feelings of guilt or responsibility. About one third of adults report experiencing psychological abuse by an intimate partner during their lifetime (Smith et al., 2018).

Whereas physical violence may be episodic, psychological abuse is frequently more unrelenting. Over time, psychological abuse is devastating to an individual's self-esteem and self-confidence and can lead to psychiatric and physical disorders resulting from chronic stress. The varieties of abuse used to exert power and control over romantic partners are represented in [Figure 23.1](#).

KEYCONCEPT Teen Partner Abuse Teens and adults are often not aware of the frequency with which teen dating violence occurs. In a recent national survey of adolescents in the United States, 1 in 11 female and 1 in 15 male high school students reported having experienced physical violence by a dating partner in the last year (Centers for Disease Control and Prevention [CDC], 2020a). Sexual violence is also prevalent, reported by 1 in 9 female and 1 in 36 male students. Conflict or relationship problems with parents and peers may be predictors of teen partner abuse. Teens who experience violence in intimate relationships are more likely to develop problems such as depression, substance abuse, eating disorders, and thoughts of suicide. School performance may suffer. Dating violence places youths at higher risk for victimization during college and in subsequent relationships throughout adulthood.

Comorbidities

Besides injuries and death, survivors suffer multiple conditions directly caused by IPV or the chronic stress associated with it. Anxiety disorders, depression, posttraumatic stress disorder, and substance use disorders are all associated with family violence. Examples of health problems associated with IPV include

asthma, gastrointestinal conditions, cardiovascular problems, bladder infections, migraines, joint pain, gynecological disorders, and sexually transmitted diseases (STDs) (Office of Women's Health, 2019). Strangulation and blows to the head can cause traumatic brain injuries that have lasting effects on cognition and functioning.

Risk Factors for Intimate Partner Violence

IPV occurs across all demographics and socioeconomic levels. Younger women, women who are divorced or separated, and Native American and Alaska Native women are at highest risk (National Center for Victims of Crime, n.d.). Although women are disproportionately affected, men can also be victims of IPV. Nonheterosexual couples experience IPV at rates similar to heterosexual couples, but victims often receive less support because of social stigma associated with nontraditional relationships. Within any type of relationship, frequent conflicts, jealousy, and possessiveness are associated with an increased risk of violence.

Individual characteristics such as low self-esteem, emotional insecurity, antisocial or borderline personality traits, disorders such as depression and posttraumatic stress disorder or a history of violence increase the likelihood of perpetration of violence (CDC, 2019). There is a strong association of substance use, especially alcohol abuse, with family violence. The presence of firearms in the home increases the risk of lethal violence.

FIGURE 23-1: Power and control wheel.(Courtesy of Domestic Abuse Intervention Programs, 202 East Superior Street, Duluth, MN. 55802 218-722-2781 www.theduluthmodel.org)

Personal stressors, such as low income and unemployment, and external stressors, such as natural disasters or economic crises, may challenge individual and family coping, resulting in violence (CDC, 2019). In unstable families, violence sometimes begins or escalates when a pregnancy occurs. Abuse during pregnancy is a significant risk factor for several fetal and maternal complications, including miscarriages, low birth weight, low maternal weight gain, infections, and anemia (Alhusen et al., 2015). Pregnancy is a window of opportunity for health care providers to screen women for IPV and refer them to the appropriate services.

Impact of the Coronavirus Disease 2019 Pandemic

The coronavirus disease 2019 pandemic resulted in significant psychosocial, health, and economic stressors; decreased contact with social support networks; and disruptions to services. For people in abusive relationships, extended time in contact partners increases the likelihood that violence will occur. Similarly, the absence of school and childcare resources may heighten the risk of child abuse and prevent abuse from being identified. School closures, scarce resources, misinformation in the media, fewer leisure outlets, and changes in job status contribute to family stress and conflict. When stay-at-home orders are in place and agencies are closed, seeking safety and support is more challenging, and travel restrictions can hinder escape plans. There are fewer opportunities to reach out for assistance when the abusive partner is consistently present, often monitoring communications. Abusive partners can withhold access to medications, supplies, or insurance cards to control their victims. Survivors who are at-risk medically might fear leaving their homes to seek assistance. Calls to domestic violence support hotlines have increased nationally, as have domestic violence calls in some police jurisdictions (Ramaswamy et al., 2020). Shelters, which are deemed “essential businesses,” remain open. Demand for domestic violence services has historically risen after natural disasters have subsided. Unfortunately, meeting anticipated needs will be challenging, as prior to the pandemic, the capacities of the nearly 1,900 domestic violence programs across the United States were already strained.

KEYCONCEPT Sexual violence includes any form of nonconsenting sexual activity, ranging from verbal threats to penetration.

Sexual Violence

Sexual violence is any type of sexual activity inflicted on a nonconsenting person. Sexual violence can include acts that are not identified as illegal but that are nevertheless traumatic or harmful in that the victim feels objectified, unsafe, or without choice. **Rape** and sexual assault are criminal acts. Rape specifically refers to vaginal, oral, or anal penetration, no matter how slight, with a body part or object, without consent of the victim (Bureau of Justice Statistics, n.d.). In

2013, the rape law was changed to be gender neutral and to state that physical force was not required for a perpetrator to be criminally charged. Rapists sometimes use coercion or threats to gain control over their victims. Rape is a crime of violence and domination, with sexuality used as a weapon. Sexual assault includes a broad range of behavior involving unwanted contact of a sexual nature. Sexual activity that occurs with a person who is unable to consent because of age, mental status, or impairment is considered sexual assault. When the victim is a minor, sexual assault is often referred to as sexual abuse. Most sexual assaults are perpetrated by someone known to the victim. Children are most likely to be sexually abused by family members, caregivers, or others close to them, as are older adults and adults with disabilities. Adolescents and young adults are especially vulnerable to drug-facilitated assault by acquaintances, which involves the use of “date-rape” drugs, often combined with alcohol, to make a victim incapable of resistance. It is common for sexual assault to occur in conjunction with IPV, as an additional means of intimidation and humiliation. Non-consensual sex within a marriage was exempt from rape laws until the 1970s, and it was not until 1993 that all states had removed that exemption (England, 2020).

Stalking

Stalking is a pattern of repeated unwanted contact, attention, and harassment that often increases in frequency. Stalkers harass and terrorize their victims through behavior that causes fear or substantial emotional distress. Stalking may include such behaviors as following someone, showing up at the person’s home or workplace, vandalizing property, using technology to track or harass someone, or sending unwanted gifts. One in 6 women and one in 19 men experience stalking at some point in their lifetime (Smith et al., 2018). Stalking can be prolonged and takes a tremendous toll on victims’ health and functioning.

Child Abuse and Neglect

Child abuse includes acts of commission and acts of omission. Acts of commission are intentional harmful behaviors directed toward a child and include physical, sexual, and psychological abuse. **Child neglect** is an act of

omission, which occurs when a child's basic physical, emotional, educational, and health care needs are not met. Failure to protect a child from harm, inadequate supervision, or exposure to violence are other forms of neglect (CDC, 2020b). Neglect is the most common form of child abuse.

Children who are younger than 4 years of age, who are products of unwanted pregnancies, or who have developmental or physical disabilities are at highest risk of abuse (CDC, 2020b). Young parents who lack social support, resources, and knowledge of normal childhood development are at increased risk of abusing their children. Multiple stressors, emotional or substance abuse problems, and the use of harsh punishment are additional parental risk factors.

Children who are abused or neglected may develop physical, emotional, and behavioral problems (CDC, 2020b). Their cognitive development may be impaired, and they may exhibit academic difficulties. Abuse leads to problems getting along with or trusting others. Survivors of child abuse are at increased risk for depression, anxiety, low self-esteem, and substance abuse. Adverse experiences in childhood have a negative impact on health and well-being throughout life.

A child who is emotionally or psychologically abused does not have visible injuries to alert others. Nevertheless, psychological abuse severely affects a child's self-esteem and often leaves permanent emotional scars. For many survivors of childhood abuse, emotional abuse is worse than physical abuse. Psychological abuse frequently co-occurs with other types of abuse and can take various forms. Children often believe the abuse is their fault.

Sexual abuse occurs to children of all ages and is frequently perpetrated by someone the child knows and trusts. To maintain their silence, children may be threatened or told that they will not be believed if they disclose the abuse. No child is psychologically prepared to cope with repeated sexual stimulation. A victim of prolonged sexual abuse will develop low self-esteem, a feeling of worthlessness, and a distorted view of sex. The child may become withdrawn, distrustful, or suicidal. Other characteristics of children who have been sexually abused include an unusual interest or avoidance of sexually related content, nightmares, seductiveness, refusal to go to school, conduct problems, secretiveness, and unusual aggressiveness (American Academy of Child & Adolescent Psychiatry, 2020).

Abuse of Older Adults

Older adults and adults who have mental or physical disabilities are vulnerable to abuse. Older individuals may be victims of physical, psychological, or sexual abuse. The most common type of elder abuse is financial abuse, in which older adults may be manipulated by family or caregivers to give up control of their money and are vulnerable to scams and fraud perpetrated by outsiders.

Elder abuse is increasingly recognized as a serious problem in the United States and other countries. As the population continues to age, it is likely that the problem will worsen. The actual prevalence of elder abuse is uncertain, as most abuse is unreported, and relatively little research has focused on this population. An estimated 1 in 10 people over age 60 who live at home suffer some type of abuse, including neglect and exploitation (CDC, 2020c). The abuse usually occurs at the hands of a caregiver or a person the older adult trusts but is a significant problem in nursing homes and assisted living facilities as well.

Individuals who are isolated, have poor support systems, or have mental or physical impairments that foster dependency on others are more vulnerable to harm. Older people may be reluctant to report maltreatment by those they love or on whom they depend, or cognitive deficits may prevent them from being able to articulate their situation. In addition to the obvious physical problems (e.g., injuries, pressure sores, malnutrition) that can result from abuse or neglect, older adults can experience worsening of existing medical conditions and emotional problems such as depression, anxiety, and fearfulness (CDC, 2020c).

Risk factors for those who are more likely to abuse older adults include using drugs or alcohol, high levels of stress, lack of social support, emotional or financial dependence on the older adult, lack of training in taking care of older adults, and depression (CDC, 2020c). Caring for a dependent older adult can be overwhelming. It is important for the nurse to listen to and assess both older adults and their caregivers to help prevent abuse and neglect in this population.

THEORIES OF VIOLENCE

No single cause is sufficient to explain the phenomenon of family violence. The neurobiologic and psychological factors that contribute to anger and poor impulse control (as outlined in [Chapter 13](#)) are relevant to the use of aggression

in the home. However, the ability of many abusers to refrain from angry outbursts and violence in public settings suggests that their behavior toward family members is not solely attributable to poor self-control. The risk factors discussed in previous sections increase the likelihood of violence occurring but do not cause it. Many people share the same risks but do not engage in violence. Outlined below are a few prominent theories among the many researchers that attempt to explain IPV and other types of violence in the family. Individual characteristics likely intersect with risk factors to produce behavior that is learned and reinforced in families, communities, and society.

Social Learning Theory (Intergenerational Transmission of Violence)

Being a victim of childhood abuse is one of the strongest predictors of violence as an adult. Violent families create an atmosphere of tension, fear, intimidation, and confusion about intimate relationships. Children in violent homes learn that violent behavior is an approved and legitimate way to solve problems and to cope with difficulty. Social learning or **intergenerational transmission of violence** theory posits that children who witness or experience violence in their homes are more likely to perpetuate violent behavior within their own families (Copp et al., 2016). Experiencing harsh physical discipline increases the risk of perpetrating family violence as an adult (Afifi et al., 2017). This learned behavior is reinforced when violence as a means of control or punishment is sanctioned within social systems or when there are inadequate social or legal constraints to discourage such behaviors.

Economic Disadvantage, Community Disorganization, and Attitudes Supportive of Violence

Neighborhoods that are more socially cohesive are more intolerant of deviant behavior. The presence of concentrated economic disadvantage (i.e. neighborhoods with the lowest incomes, high unemployment, and institutional disinvestment); racial or ethnic heterogeneity; and community instability is associated with community disorganization and weak social control, which leads

to increased levels of crime and IPV. Within these disadvantaged communities, institutions that normally foster social control, such as churches, schools, and other community organizations, lose their ability to exercise social control over the community. Community disorganization, crime, and weak social control also foster individual acceptance of violence, which, in turn, is associated with increased rates of IPV, child abuse, and elder abuse (Copp et al., 2016).

Imbalances in Relationship Power

Another body of literature suggests that IPV is a manifestation of gender-based imbalances in relationship power. Usually, this perspective explains IPV as violence against women by their male romantic partners related to issues of gender, inequality, power and privilege, patriarchy, and the subordination of women (Namy et al., 2017). Patriarchal systems exist and are supported at the macro level (e.g., government, bureaucracies, religion) and at the micro level (e.g., families), and both levels have gender inequities. Within a patriarchal society, men often hold traditional gender role beliefs. For example, whereas men are heads of households and provide for their families, women are homemakers and mothers. When these beliefs are challenged, such as when women enter the workforce and earn more than their partner, men may feel threatened and respond with violence.

Historically, women and children had few or no rights in most cultures, and in many countries today, women's rights remain limited (Ramsey, 2011). Women and children were considered part of the household over which the male held absolute power and violence was accepted as a permissible way to exercise authority. Even after popular opinion changed and so-called wife-beating became formally illegal in all states in the United States by 1920, IPV was treated differently than other crimes and viewed as a private matter that rarely resulted in arrest or prosecution until the latter part of the 20th century. Until recently, men in the United States were able to use physical violence with relative impunity within the context of intimate relationships. In 1994, *The Violence Against Women Act* (VAWA) (P.L. 103–122) became the first U.S. federal policy to combat interpersonal violence and other violence against women. This law declared civil rights for victim-survivors of gender-based violence and created new laws to protect them. The law has been reauthorized several times, with revisions to extend increasingly inclusive protections;

however, it expired in early 2019 and as of mid-2020 has not been reauthorized by the current Senate. This is critical because VAWA provides funding for domestic violence services and legal protections for immigrants and other marginalized populations. Despite changes in laws, patriarchal attitudes continue to influence the dynamics of some families, sometimes bolstered by cultural and religious norms (Ogunsiji & Clisdell, 2017).

Cycle of Violence

Many, but not all, cases of IPV reflect a recognized **cycle of violence**. The cycle consists of three recurring phases that often increase in frequency and severity. The cycle is fully described in [Figure 23.2](#).

Factors Influencing Leaving Versus Staying in a Violent Relationship

Many women do not report abuse, fearing retaliation against themselves or their children. Often, they continue to hold strong feelings for their partners despite the abuse. When medical care is required, women may attribute their injuries to other causes; health care providers may be reluctant to inquire about abuse. Provision of assistance to women who are involved in violent intimate relationships can pose unique problems in that seeking support can be dangerous to the women if their activities are discovered by the abusive partner. Therefore, the challenge for health care providers is twofold—ensuring that support is both available and safely accessible, whether or not it is accepted at a given time. Even though it might be difficult to understand why a person would remain in an abusive relationship, it is critical to remain nonjudgmental and to realize that there are valid reasons for deciding to remain in a potentially harmful environment.

Leaving an abusive relationship is a process that can be quite complex. Many women leave and return several times as they learn new coping skills and build support networks before ending the relationship permanently. When abuse is intermittent, and strong emotional and psychological ties to the abusive partner remain, victims continue to hope that the behavior will change. Women who lack

job skills, financial resources, and support systems may stay because of economic dependence on their partner. Some are concerned about losing custody of their children if they are unable to provide for them independently.

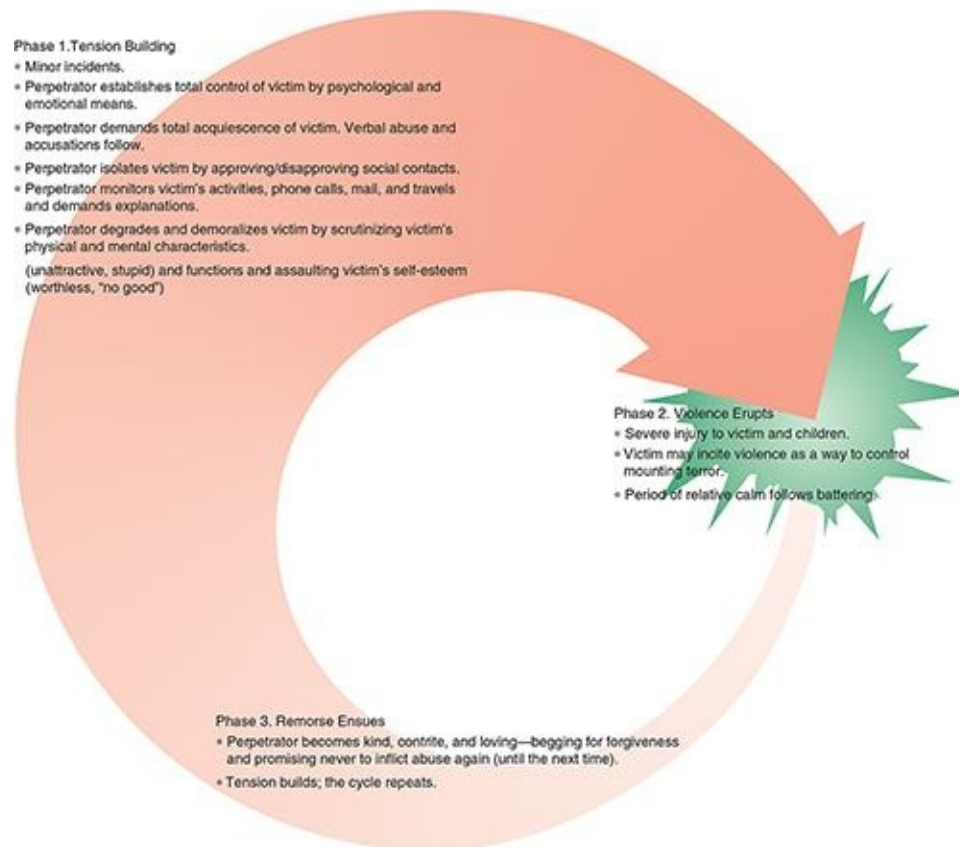

FIGURE 23-2: The cycle of violence

Fear is another important factor in deciding whether to leave or stay in a violent relationship. Some women stay because of threats not only against themselves but also against other family members or pets. Women recognize the valid concern that leaving may not stop the violence. If victims attempt to leave or actually do leave the relationship, perpetrators often escalate their violence, stalk their partners, and may even kill them, which makes leaving the time of greatest risk in an abusive relationship (National Coalition against Domestic Violence [NCADV], n.d.).

Safety Issues and Mandatory Reporting

Health care providers, including nurses, are mandated reporters. This means that they must report known or suspected abuse in specific circumstances. Some states require reporting of injuries sustained as a result of abuse. Mandatory reporting for IPV is controversial because it may act as a barrier to disclosure or seeking care (Lippy et al., 2020). Concerns center around triggering involvement with the legal system that can result in removal of children from custody, loss of economic support, or retaliation from the abuser. Black mothers are disproportionately likely to be referred to child protective services for IPV-related concerns. Immigrants, especially those who are undocumented, may fear that discussing IPV will lead to contacts with immigration authorities and deportation or separation from their children.

All states require reporting of known or suspected abuse involving children and vulnerable adults. It is important for nurses to be familiar with the laws of the state in which they practice and with the policies of their organization. Removing children and older adults from their families or caregivers may be necessary to ensure their immediate safety. In most settings, nurses do not have to make this decision alone; rather, they involve other professionals to assist with assessment and alternate placement if the current living situation of an abused or neglected child or older adult cannot be made safe. When an older adult's decision-making is not impaired (*competence* is the legal term), they must be allowed an appropriate degree of autonomy in deciding how to manage the problem even if they choose to remain in the abusive situation (Pomerance, 2015). Forcing someone to do something against their wishes is itself a form of victimization by denying autonomous decision-making.

THE ROLE OF TECHNOLOGY IN CARING FOR SURVIVORS OF INTIMATE PARTNER VIOLENCE

For survivors of violence, technology can be a weapon or a lifeline. Abusers can use technology, to monitor their partner's activities or threaten to post compromising photos or confidential information on a public forum as a means of control. More often, the internet is a valuable source of information and support when using reliable sources such as hotlines, particularly for survivors who are not emotionally ready for in-person meetings or who do not have ready

access to nearby services. For those who are in abusive relationships, websites, 24-hour hotlines, and chats provide resources for safety planning (Rempel et al., 2019). Most websites and chats designed for IPV survivors have escape features to disconnect quickly if necessary. Survivors are warned to clear their search histories if there is a risk they are being checked. Technology extends the reach of services for survivors in rural and underserved locations via virtual therapy and consultations, and peer support can come through online groups and texts and messaging apps.

When connecting with a survivor online, confidentiality is crucial. Therapists are careful to use secure platforms that cannot be tracked or monitored. Telemedicine providers should be aware of risks when incorporating screening questions into the visit. Yes or no questions can be used to ensure that the client is alone and it is safe to speak. If a survivor is at risk, messages can be moved to password-protected health portals. When language is a barrier, it is important to utilize certified interpreters who are not family members. Virtual access to services and health care became critical when controlling the spread of the new coronavirus required social distancing and limitation of in-person services. These situations increased safety risks for survivors of IPV and expanded use of technology created opportunities to reduce isolation. In all cases, effective use of technology requires internet or mobile access, which is not universally available.

THERAPEUTIC RELATIONSHIP

Establishing a trusting nurse–patient relationship is one of the most important steps in caring for any person experiencing violence. When interviewing, to establish rapport and put the survivor at ease, start with the least sensitive areas and progress to more sensitive topics (Power, 2017). Survivors are unlikely to disclose sensitive information unless they perceive the nurse to be trustworthy and nonjudgmental. Important considerations in establishing open communication are ensuring confidentiality and providing a quiet, private place in which to interact. A supportive, empathetic approach is most effective. The nurse must continually monitor personal reactions to prevent negative feelings from influencing the nurse–patient relationship in a way that could re-traumatize the survivor. Nurses must make clear during the assessment their responsibility for mandated reporting.

EVIDENCE-BASED NURSING CARE FOR PERSONS EXPERIENCING VIOLENCE

Nurses encounter survivors of violence and abuse in many health care settings, not just in mental health settings. Abuse may be disclosed or discovered by providers in urgent care clinics, primary care settings, obstetrics and gynecology settings, pediatric units, well-child clinics, geriatric units, schools, and nursing homes, among others.

Mental Health Nursing Assessment

Conducting a Safety Assessment First

Once physiologic stability is established, the nurse should determine whether the survivors are in danger for their life, either from homicide or suicide, and, if children are in the home, whether they are in danger. Trauma may trigger suicidal ideation or exacerbate preexisting mental health conditions that place the survivor at risk. Suicide precautions should be initiated if indicated.

Children who are present during abusive episodes are at risk for emotional and developmental harm even if they are not direct recipients of abuse. Exposing a child to violence carries legal consequences in many states (Child Welfare Information Gateway, 2016).

The Danger Assessment Screen is a useful tool for assessing the risk that IPV will end in homicide (Campbell & Humphries, 1993) ([Box 23.1](#)). This assessment may help survivors recognize the serious nature of the violence they routinely experience. An abbreviated version of this tool, the Danger Assessment-5 (Messing et al., 2017), can be used for brief screening.

BOX 23.1

Danger Assessment

Several risk factors have been associated with homicides (murders) of both batterers and victims in research that has been conducted after the killings have taken place. We cannot predict what will happen in your case, but we would like you to be aware of the danger of homicide in situations of severe battering

and to see how many of the risk factors apply to your situation.

1. Has the physical violence increased in frequency during the past year?
2. Has the physical violence increased in severity during the past year or has a weapon or threat with weapon been used?
3. Does your partner ever try to choke you?
4. Is there a gun in the house?
5. Has your partner ever forced you to have sex when you did not wish to do so?
6. Does your partner use drugs? By drugs, I mean “uppers” or amphetamines, speed, angel dust, cocaine, “crack,” street drugs, heroin, or mixtures.
7. Does your partner threaten to kill you, or do you believe they are capable of killing you?
8. Is your partner drunk every day or almost every day? (In terms of quantity of alcohol.)
9. Does your partner control most or all of your daily activities? For instance, does they tell you who you can be friends with, how much money you can take with you for shopping, or when you can take the car?
10. Has your partner ever beaten you while you were pregnant? (If never pregnant by him, check here _____.)
11. Is your partner violently and constantly jealous of you? (For instance, do you? (For instance, say, “If I can’t have you, no one can.”)
12. Have you ever threatened or tried to commit suicide?
13. Have they ever threatened or tried to commit suicide?
14. Is your partner violent toward the children?
15. Is your partner violent outside the home?

TOTAL YES ANSWERS: _____

Thank you. Please talk to your nurse, advocate, or counselor about what the danger assessment means in terms of your situation.

Screening for Violence and Abuse

Because of the prevalence of IPV, the US Preventive Services Task Force recommends universal screening for all women of child-bearing age (2018). However, actual rates of screening in most settings are low. Most survivors do not report violence to health care workers without specifically being asked about it (Power, 2017). Survivors may be reluctant to report abuse because of shame, embarrassment, fear of not being believed, or fear of retaliation. Survivors who depend on the abuser for care or financial support may be concerned about consequences of disclosure. If the suspected abuser is present, it is important to speak to the survivor alone.

Validated screening tools are readily accessible (Cavner, 2019). Asking specific abuse screening questions substantially increases the detection of abuse.

For that reason, nurses must develop a repertoire of age-appropriate, culturally sensitive abuse-related questions. Avoid using terms such as *abuse* and *rape*, because those labels may not be consistent with an individual's perception of their experience. See [Boxes 23-2](#) and [23-3](#).

Other questions that might be useful in eliciting disclosure are as follows:

- “When there are fights at home, have you ever been hurt or afraid?”
- “It looks like someone has hurt you. Tell me about it.”
- “Some women have described problems like yours. If this is happening to you, can we talk about it?”

When survivors are disclosing abuse, they need privacy and time to tell their story. The nurse should listen attentively without offering unsolicited advice or making judgmental remarks about the possible abuse or the perpetrator. Use validating messages to convey that the survivors are believed and that the nurse is concerned for their safety and well-being. Examples of such messages include the following:

- “I’m really sorry this happened to you.”
- “I’m glad you told me.”
- “It sounds like a frightening experience.”
- “It was not your fault.”

BOX 23.2

Abuse Assessment Screen

1. Have you ever been emotionally or physically abused by your partner or someone important to you?	YESNO
2. Within the past year, have you been hit, slapped, kicked, or otherwise physically hurt by someone?	YESNO
If YES, by whom: _____	
Number of times: _____	
Mark the area of injury on body map.	
3. Within the past year, has anyone forced you to have sexual activities?	YESNO
If YES, who: _____	
Number of times: _____	
4. Are you afraid of your partner or anyone you listed above?	YESNO

BOX 23.3

Burgess-Partner Abuse Scale for Teens

Directions: During the past 12 months, you and one of your partners may have had a fight. Following is a list of things one of your partners may have done to you. Please circle the number of how often this partner did these things to you. This is not a test and there are no right or wrong answers. Remember, having a partner(s) does not mean you are having sex with the partner(s).

If you have not had a partner in the past 12 months, do not fill this form out.

	Never	Once	A Few	More than a	Routinely
			Times	Few Times	or a lot
	0	1	2	3	4
1. My partner doesn't let me go out with my friends.	0	1	2	3	4
2. My partner tells me what to wear.	0	1	2	3	4
3. My partner says if I don't have sex with them then I don't love them.	0	1	2	3	4
4. My partner says they will hurt me if I talk to another guy/girl.	0	1	2	3	4
5. My partner calls me bad names like bitch.	0	1	2	3	4
6. My partner says they will hurt me with a weapon.	0	1	2	3	4
7. My partner forces me to have sex.	0	1	2	3	4
8. My partner tells me I am stupid or dumb.	0	1	2	3	4
9. My partner follows me when I do things with my friends or family.	0	1	2	3	4
10. My partner hits or kicks something when they get mad at me.	0	1	2	3	4
11. My partner kicks me.	0	1	2	3	4
12. My partner says they can have sex with other people even though they said I can't.	0	1	2	3	4
13. My partner gives me sexually transmitted infections.	0	1	2	3	4
14. My partner hurts me using a weapon.	0	1	2	3	4
15. My partner forces me to use drugs	0	1	2	3	4

eventhough I don't want to.					
16.My partner beats me up so bad.	0	1	2	3	4
17.My partner says they will hurt my family if I don't do what they say.	0	1	2	3	4
18.My partner tells me what school activities I can and can't do.	0	1	2	3	4
19.My partner tells me what friends I can hangout with.	0	1	2	3	4
20.My partner chokes me if they get mad at me.	0	1	2	3	4
21.My partner yells at me if they don't know where I am.	0	1	2	3	4
22.My partner says we can't break up eventhough I want to.	0	1	2	3	4

How many partners have you had in the past 12 months? _____

Permission is granted for use in research or clinical settings. Burgess, S., & Tavakoli, A. (2005).

Psychometric assessment of the Burgess-Partner Abuse Scale for Teens (B-PAST). Aquichan, 5, 96–107.

Survivors of IPV may deny the abuse, make excuses for the perpetrator's behavior, or attribute an injury to an unlikely cause. Avoid pressuring or confronting them, but carefully document a description of the survivor's account of how the injury happened, using the survivor's own words.

After assessment is completed in a health care agency and abuse is evident, the nurse should offer the adult survivor use of the telephone. This may be the only time that the survivor can make calls in private to family, who might offer support, or to the police, lawyers, or shelters. Scheduling future appointments may provide the survivor with a legitimate reason to leave the perpetrator and continue to explore options.

Physical Health Assessment

Documentation of abuse or suspected abuse includes a complete history and physical examination. Note vital signs, sleep and appetite disturbances, exaggerated startle responses, flashbacks, and nightmares that may suggest PTSD or depression. Assess for injuries in need of immediate attention. Documentation should include a detailed history of how injuries occurred and a

Careful description of the injuries. A body map may be used to indicate location, size, and type of injuries. The nurse's documentation may become evidence if there are legal consequences related to the violence, even if the survivor declines to file a report at the time of the incident. Victims of violence experience mild-to-severe physical consequences. Mild injuries may include bruises and abrasions of the head, neck, face, trunk, and limbs. People who are chronically abused may have multiple bruises in various stages of healing. Severe injuries include multiple traumas, major fractures, major lacerations, and internal injuries (including chest and abdominal injuries and subdural hematomas). Loss of vision and hearing can result from blows to the head.

Physical or sexual violence may result in head injuries that can produce changes in cognition, affect, motivation, and behavior. Survivors of sexual abuse may have vaginal and perineal trauma. Anorectal injuries may also be present, including disruption of anal sphincters, retained foreign bodies, and mucosal lacerations. Examination for sexual abuse, acute or chronic events, may require referral to a trained registered nurse in sexual assault, known as a sexual assault nurse examiner (SANE). If a SANE nurse is not available, the Emergency Department nurse may take the lead in caring for patients who have experienced sexual assault. Sexual assault examination involves evidence gathering, careful documentation, and attention to psychosocial needs and emotional distress (Delgadillo, 2017). Determine the need for emergency contraception, or prophylactic treatment for human immunodeficiency virus [HIV] or STDs. See [Box 23-4](#) for additional considerations.

BOX 23.4

Special Concerns for Victims of Sexual Assault

ASSESSMENT FOCUS

The history and physical examination of the survivor of sexual assault differ significantly from other assessment routines because the evidence obtained may be used in prosecuting the perpetrator. Therefore, the purpose is twofold:

- To assess the patient for injuries
- To collect evidence for forensic evaluation and proceedings

Usually, someone with appropriate training, such as a nurse practitioner who has taken special courses, examines a victim of rape or sexual assault. Generalist nurses may be involved in treating the injuries that result from the assault, including genital trauma (e.g., vaginal and anal lacerations) and extragenital trauma (e.g., injury to the mouth, throat, wrists, arms, breasts, thighs).

KEY INTERVENTIONS

Nursing intervention to prevent short- or long-term psychopathology after sexual assault is crucial. Psychological trauma after rape and sexual assault includes immediate anxiety and distress and the development of PTSD, depression, panic, and substance abuse.

Key interventions include the following:

- Early treatment because initial levels of distress are strongly related to later levels of posttraumatic stress disorder, panic, and anxiety.
- Supportive, caring, and nonjudgmental nursing interventions during the forensic rape examination are also crucial. This examination often increases survivors' immediate distress because they must recount the assault in detail and submit to an invasive pelvic or anal examination.
- Anxiety-reducing education, counseling, and emotional support, particularly regarding unwanted pregnancies and sexually transmitted infections, including HIV. All survivors should be tested for these possibilities. Treatment may include terminating a pregnancy; administering medications to treat gonorrhea, chlamydia, trichomoniasis, and syphilis; and administering medications that may decrease the likelihood of contracting HIV infection.
- Interventions that are helpful for survivors of domestic violence; these also apply to survivors of sexual assault.

Healthy child development and deviations that may be related to abuse or neglect are critical components of the nursing assessment of children. Assessing developmental milestones, school history, and relationships with siblings and friends is important. Intracranial hemorrhage in an infant in the absence of an obvious cause, such as a motor vehicle accident, may suggest shaken baby syndrome. Infants do not begin to move or ambulate on their own prior to the age of 6 months, when they begin to crawl; therefore, any bruises on an infant before the age of 6 months is cause for suspicion. Any discrepancies between the history and physical examination and implausible explanations for injuries and other symptoms should be an alert to the possibility of abuse (Yaffe, 2010). Children and adolescents who wear clothing that covers parts of the body in a manner inconsistent with the season may be hiding bruises, abrasions, or burns caused by cigarettes or boiling water. Other circumstances that should heighten the suspicion of childhood abuse include multiple fractures or types of fractures (such as spiral fractures) that would only occur in an abusive situation. Other injuries such as bite marks or injuries to the genitals or anus always require further investigation.

For reference when assessing older adults, become familiar with normal aging and signs and symptoms of common illnesses to distinguish those conditions from abuse. Observe for signs of malnutrition or inattention to activities of daily living (ADLs). As with children, bruises, lacerations, and other injuries are suspicious if they are inconsistent with a description of how they occurred. Some older adults are unable to communicate effectively because of dementia or other

cognitive impairment. Evidence that excessive medications or physical restraints are being used to control an older adult's behavior should be investigated. [Box 23-5](#) lists indicators of actual or potential abuse that need to be thoroughly assessed for all survivors.

BOX 23.5

History and Physical Findings Suggestive of Abuse

PRESENTING PROBLEM

- Vague information about cause of problem
- Delay between occurrence of injury and seeking of treatment
- Inappropriate reactions of significant other or family
- Denial or minimizing of seriousness of injury
- Discrepancy between history and physical examination findings

FAMILY HISTORY

- Past family violence
- Physical punishment of children
- Children who are fearful of parent(s)
- Father or mother (or both) who demands unquestioning obedience
- Alcohol or drug abuse
- Violence outside the home
- Unemployment or underemployment
- Financial difficulties or poverty
- Use of older adult's finances for other family members
- Finances rigidly controlled by one member

HEALTH AND PSYCHIATRIC HISTORY

- Fractures at various stages of healing
- Spontaneous abortions
- Injuries during pregnancy
- Multiple visits to the emergency department
- Elimination disturbances (e.g., constipation, diarrhea)
- Multiple somatic complaints
- Eating disorders
- Substance abuse
- Depression
- Posttraumatic stress disorder
- Self-mutilation
- Suicide attempts
- Feelings of helplessness or hopelessness
- Low self-esteem
- Chronic fatigue
- Apathy
- Sleep disturbances (e.g., hypersomnia, hyposomnia)

- Psychiatric hospitalizations

PERSONAL AND SOCIAL HISTORY

- Feelings of powerlessness
- Feelings of being trapped
- Lack of trust
- Traditional values about home, partner, and children's behavior
- Major decisions in family controlled by one person
- Few social supports (isolated from family, friends)
- Little activity outside the home
- Unwanted or unplanned pregnancy
- Dependency on caregivers
- Extreme jealousy by partner
- Difficulties at school or work
- Short attention span
- Running away
- Promiscuity
- Child who has knowledge of sexual matters beyond that appropriate for age
- Sexualized play with self, peers, dolls, toys
- Masturbation
- Excessive fears and clinging in children
- Verbal aggression
- Themes of violence in artwork and schoolwork
- Distorted body image
- History of chronic physical or psychological disability
- Inability to perform activities of daily living
- Delayed language development

PHYSICAL EXAMINATION FINDINGS

General Appearance

- Fearful, anxious, hyperactive, hypoactive
- Watching partner, parent, or caregiver for approval of answers to your questions
- Poor grooming or inappropriate dress
- Malnourishment
- Signs of stress or fatigue
- Flinching when approached or touched
- Inappropriate or anxious nonverbal behavior
- Wearing clothing inappropriate to the season or occasion to cover body parts

Vital Statistics

- Elevated pulse or blood pressure
- Other signs of autonomic arousal (e.g., exaggerated startle response, excessive sweating)
- Underweight or overweight

Skin

- Bruises, welts, edema, or scars
- Burns (cigarette, immersion, friction from ropes, pattern like an electric iron or stove)
- Subdural hematoma
- Missing hair

- Poor skin integrity: dehydration, decubitus ulcers, untreated wounds, urine burns, or excoriation

Eyes

- Orbital swelling
- Conjunctival hemorrhage
- Retinal hemorrhage
- Black eyes
- No glasses to accommodate poor eyesight

Ears

- Hearing loss
- No prosthetic device to accommodate poor hearing

Mouth

- Bruising
- Lacerations
- Missing or broken teeth
- Untreated dental problems

Abdomen

- Abdominal injuries during pregnancy
- Intraabdominal injuries

Genitourinary System or Rectum

- Bruising, lacerations, bleeding, edema, tenderness
- Untreated infections

Musculoskeletal System

- Recent fractures or old fractures in various stages of healing
- Dislocations
- Limited range of motion in extremities
- Contractures

Neurologic System

- Difficulty with speech or swallowing
- Hyperactive reflexes
- Developmental delays
- Areas of numbness
- Tremors

Mental Status

- Anxiety, fear
- Depression
- Suicidal ideation
- Difficulty concentrating
- Memory loss

Medications

- Medications that are not indicated by physical condition
- Overdose of drugs or medications (prescribed or over the counter)
- Medications not taken as prescribed

Communication Patterns and Relations

- Verbal hostility, arguments
- Negative nonverbal communication, lack of visible affection
- One person answers questions and looks to other person for approval
- Extreme dependency of family members

Psychosocial Assessment

Fear

Living with an abusive partner, parent, or caregiver means living with constant fear and uncertainty. Because victims never know what might precipitate an incident of violence, they are constantly hypervigilant and fearful. The back-and-forth nature of the relationship, that is, alternating between love and violence, is confusing, so the survivor may try to do everything possible to please the abuser in an effort to prevent another violent episode.

Low Self-Esteem

Being the victim of abuse is devastating to healthy self-esteem, or feelings of self-acceptance, self-worth, self-love, and self-nurturing. Emotional abuse may be particularly devastating. Victims are criticized, rejected, devaluated, and ignored. Over time, people begin to internalize the negative messages and may come to believe the abuse is deserved. Low self-esteem has been linked to physical and mental health problems, problems with relationships, may affect survivors' ability to achieve financial independence.

Guilt and Shame

A history of abuse is often associated with guilt and shame. Survivors are ashamed of being manipulated and violated and for having put themselves in such a situation. Abusive partners tell the survivors that the abuse is their fault and many victims believe them. Feelings of humiliation and shame prevent

survivors from seeking medical care and other forms of support and reporting abuse to authorities. The experience of being battered is so degrading and humiliating that survivors are often afraid to disclose it to anyone. Many fear that they will not be taken seriously or will be blamed for inciting the abuse or for staying with their abusers. Keeping their circumstances secret and maintaining a front of normality places enormous tension and pressure on survivors.

Problems with Intimacy

Abused children, especially those who have experienced child sexual abuse, experience intrusion, abandonment, devaluation, or pain in the relationship with the abuser instead of the closeness and nurturing that are normal for intimate relationships (American Academy of Child & Adolescent Psychiatry [AACAP], 2020). Consequently, intimacy is associated with shame and fear rather than warmth and caring and with concerns about dominance and submission rather than mutuality. Shame, in turn, is associated with being submissive, feeling devalued, and the desire to retaliate against a person who is seen as the source of humiliation. In adulthood, unresolved feelings of shame, as well as symptoms of PTSD or depression, may disrupt the development of intimacy and interfere with the ability to develop and sustain healthy relationships.

Conversely, some survivors of child abuse and child sexual abuse may engage in risky sexual behavior such as early sexual activity (before age 15 years), promiscuity, and prostitution (AACAP, 2020). These behaviors place survivors at risk for developing STDs and HIV. Survivors who engage in this type of behavior may have learned that sexual activity is a means for securing affection, intimacy, or material rewards such as money or drugs.

Revictimization

Many survivors who experienced childhood trauma are revictimized later in life. Numerous factors are related to **revictimization**, including symptoms of PTSD, dissociation, boundary issues, and feelings of self-blame and shame. Internalized stigma, victim-blaming statements, and past negative social reactions from others affect survivors' self-perception and willingness to disclose subsequent abuse (Kennedy & Prock, 2018). People with abuse histories frequently have difficulty with boundaries. During childhood abuse, they experienced frequent

boundary violations and associate those violations with intimate relationships. Excessive use of alcohol and other drugs by survivors makes them more vulnerable and less able to defend themselves. Survivors with substance use problems are more likely to enter a relationship with someone who also uses alcohol or other drugs, placing them at risk for substance-related violence. In a recent study, 82% of female prison inmates with substance use issues reported childhood trauma and revictimization after age 18. Substance use problems typically followed traumatic experiences, contributed to behavioral problems in adolescence, and continued to impair their judgment and functioning in adulthood (Mejia et al., 2015).

Social Networks

An evaluation of social networks provides additional clues of psychological abuse and controlling behavior. Having supportive family or friends is crucial in short-term planning for developing a safety plan and is also important to long-term recovery. A survivor cannot leave an abusive situation with nowhere to go. Supportive family and friends may be willing to provide shelter and safety, as well as emotional support. As part of safety planning, survivors can set up code words to make contacts aware that help is needed, or ask friends to keep belongings or documents that they may require if they leave home quickly.

Social Isolation

Many perpetrators isolate their family from all social contacts, including other relatives. Some survivors isolate themselves because they are ashamed of the abuse or fear nonsupportive responses. Nurses can assess restrictions on freedom that may suggest abuse and control by asking such questions as “Are you free to go where you want?” “Is staying home your choice?” and “Is there anything you would like to do that you cannot?”

Economic and Emotional Dependency

Women who have young children and depend on the perpetrator financially may believe that they cannot leave the abusive relationship. Those who are emotionally dependent on the perpetrator may experience an intense grief reaction that further complicates their leaving. Older adults and children often

depend on the abuser and cannot leave the abusive situation without workable alternatives.

Clinical Judgment

Violence and abuse are critical situations that need to be addressed immediately. The nurse should focus on the individual's personal safety first and any injuries that have occurred.

Mental Health Nursing Interventions

The goals of all nursing interventions in cases of violence are to prevent injury, stop the violence, ensure the survivor's safety, and restore health.

As appropriate concerning age and ability, nursing interventions should empower survivors to act on their own behalf. This must be done in a collaborative partnership. Nurses must be willing to offer support and information and not impose their own values on survivors by encouraging them to leave abusive relationships (Campbell et al., 2009). Strong psychological and economic bonds tie many survivors to their perpetrators. Moreover, adult survivors who are capable of making decisions are the experts about their situations. They are the best judges to determine the appropriate time to leave a relationship.

Intervention strategies for older adults depend on whether the individual accepts or refuses assistance and whether they can make decisions. If the person refuses treatment, it is important to remain nonjudgmental and provide information about available services and emergency contact information. If the older adult appears incapable of making decisions, then guardianship, foster care, or nursing home placement may be needed. The nurse should initiate a referral to a case manager or others who can facilitate further intervention.

Safety Planning

One of the most important interventions when caring for individuals who are in

an ongoing abusive relationship is to help survivors develop a safety plan (Domestic Violence Resource Center, 2018). The first step in developing such a plan is helping the survivor recognize the signs of danger. Changes in tone of voice, substance use, and increased criticism may indicate that the perpetrator is losing control. Detecting early warning signs helps survivors to escape before battering begins.

The next step is to devise the escape. For families at risk for violence, this may involve mapping the house for an escape route. The IPV survivor needs to have a bag packed and hidden but readily accessible that includes what is needed to get away. Important things to pack are clothes, a set of car and house keys, bank account numbers, birth certificate, insurance policies and numbers, marriage license, valuable jewelry, important telephone numbers, and money. If children are involved, the adult survivor should make arrangements to get them out safely. That might include arranging a signal to indicate when it is safe for them to leave the house and to meet at a prearranged place.

A safety plan for a child or dependent older adult might include safe places to hide and important telephone numbers, including 911 and those of the police and fire departments and other family members and friends.

Physical Health Interventions

Treatment of trauma symptoms may include cleaning and dressing burns or other wounds and assisting with setting and casting broken bones. Malnourished and dehydrated children and older adults may require nursing interventions such as intravenous therapy or nutritional supplements that alleviate the alteration in nutrition and fluid and electrolyte imbalances. Victims of sexual assault require additional considerations (see [Box 23-5](#)).

KEYCONCEPT Individuals who are experiencing IPV need their basic needs met (e.g., safety, housing, food, child care) before their psychological traumas can be addressed.

Promoting Healthy Daily Activity

Teaching sleep hygiene (i.e., practices conducive to healthy sleep patterns) and promoting exercise, leisure time, and nutrition will help battered survivors regain a healthy physical state and self-care activities. Taking care of themselves may

be difficult for survivors who have spent years trying to separate themselves from their bodies (dissociate) to survive years of abuse. Techniques such as going to bed and arising at consistent times, avoiding naps and caffeine, and scheduling periods for relaxation just before retiring may be useful in promoting sleep (Pigeon et al., 2009). Aerobic exercise is a useful technique for relieving anxiety and depression and promoting sleep.

Managing Care of Patients with Mental Health or Substance Abuse Issues

Survivors of abuse and sexual assault, and those in abusive relationships, may experience depression, anxiety, and posttraumatic stress. These disorders interfere with cognitive processes—including judgment, decision-making, and problem-solving—and impede healing even after the survivor is in a safe environment. Trauma-informed cognitive-behavioral therapy and interpersonal therapy specifically targeting psychological consequences of IPV are the most effective treatments for survivors (Arroyo et al., 2017). Refer the survivor to a qualified mental health provider for treatment.

Survivors who have a substance use disorder need referral to a treatment center for such disorders. The treatment center should have programs that address the special needs of survivors. Alcohol- and drug-dependent survivors frequently stop treatment and return to previous dysfunctional use patterns if their violence-related problems are not addressed appropriately (Ullman & Sigurvinsdottir, 2015). Survivors who are impaired by substances are at high risk for HIV infection and other infectious diseases. If survivors do not know their HIV status, they should be encouraged to get tested.

Psychosocial Interventions

Several issues must be addressed for survivors including guilt, shame, and stigmatization. These issues can be approached in several ways. Assisting survivors to verbalize their experience in an accepting nonjudgmental atmosphere is the first step. Directly challenging attributions of self-blame for the abuse and feelings of being dirty and different is another. Helping survivors to identify their strengths and validating thoughts and feelings may help to

increase their self-esteem.

Working with Children

Children may need to learn a “violence vocabulary” that allows them to talk about their abuse and assign responsibility for abusive behavior. Children also need to learn that violence is not okay, and it is not their fault. Allowing children to discuss their abuse in the safety of a supportive, caring relationship may alleviate anxiety and fear. Respond to children’s disclosures with sensitivity, belief, and a calm demeanor. Avoid pressuring children to talk or share details if they are uncomfortable (Ramamoorthy & Myers-Walls, 2013).

Reenacting the abuse through play is another technique that may be helpful in assisting children to express and work through their anxiety and fear. Play therapy uses dolls, human or animal figures, video games, or puppets to work through anxiety or fears. Other techniques include reading stories about recovery from abusive experiences (literal or metaphoric), using art or music to express feelings, and psychodrama. In addition, teaching strategies to manage fear and anxiety, such as relaxation techniques, coping skills, and imagery, may give the children an added sense of mastering their fear (National Child Traumatic Stress Network, n.d.).

Managing Anger

Anger and rage are part of the healing process for survivors. Expression of intense anger is uncomfortable for many nurses. However, anger expression should be expected from the survivor, so it is necessary to develop comfortable ways to respond. Moreover, an important nursing intervention is teaching and modeling anger expression appropriately. Inappropriate expressions of anger might drive supportive people away. Anger management techniques include appropriately recognizing and labeling anger and expressing it assertively rather than aggressively or passive-aggressively. Assertive ways of expressing anger include owning the feeling by using “I feel” statements and avoiding blaming others. Teaching anger management and conflict resolution may be especially important for children who have seen nothing but violence to resolve problems.

Coping with Anxiety

Anxiety management is a crucial intervention for all survivors. A high comorbidity exists involving trauma, PTSD, and anxiety disorders. During treatment, survivors experience situations and memories that provoke intense anxiety and must know how to soothe themselves when they experience painful feelings. Moreover, most survivors struggle with control issues, especially involving their bodies. Anxiety management skills offer one way to maintain some control over their bodies and choices. See ,[Chapter 16](#).

Finding Strength and Hope

Providing hope and a sense of control is fundamental for survivors of trauma. Help survivors find hope by assisting them to identify specific strengths and aspects of their lives that are under their control. This type of intervention may empower survivors to find options other than remaining in an abusive relationship. Interventions that focus on empowerment encourage and create opportunities for survivors to make decisions about their lives, thereby restoring a sense of autonomy and competence lost in the abusive environment (Wood, 2015).

Psychoeducation

Other nursing interventions include teaching self-protection skills, healthy relationship skills, and healthy sexuality ([Box 23-6](#)). Again, this teaching may be especially important for children who have no role models for healthy relationships. Children also need to know what constitutes controlling and abusive behavior and how to get help for abuse. Survivors also need information about resources, such as shelters for battered women, legal services, government benefits, and support networks. Before giving the survivor any written material, first discuss the possibility that if the perpetrator were to find the information in the survivor's possession, they might use it as an excuse for further battering.

Family Interventions

Family interventions in cases of child abuse focus on behavioral approaches to improve parenting skills. A behavioral approach has multiple components. *Child*

management skills help parents manage maladaptive behaviors and reward appropriate behaviors. *Parenting skills* teach parents how to be more effective and nurturing with their children. *Leisure skills* training is important to reduce stress in the household and promote healthy family time. *Household organization* training is another way to reduce stress by teaching effective ways to manage the multiple tasks that families must perform. Such tasks include meal planning, cooking, shopping, keeping health care providers' appointments (e.g., dental care, health visits, counseling) appointments, and planning family activities (National Center for Parent, Family and Community Engagement, 2015).

BOX 23.6

Abuse

When caring for the patient who has been abused, be sure to address the following topics in the teaching plan:

- Cycle of violence
- Access to shelters
- Legal services
- Government benefits
- Support network
- Symptoms of anxiety, dissociation, and PTSD
- Safety or escape plan
- Relaxation
- Adequate nutrition and exercise
- Sleep hygiene
- HIV testing and counseling

Anger control and stress management skills are important parts of behavioral programs for families. Anger control programs teach parents to identify events that increase anger and stress and to replace anger-producing thoughts with more appropriate ones. Parents learn self-control skills to reduce the expression of uncontrolled anger. Stress-reduction techniques include relaxation techniques and methods for coping with stressful interactions with their children.

Community Involvement

Nurses may be involved in interventions to reduce violence at the community

level. Many abusive caregivers, parents, and guardians, as well as battered partners, older adults, and children are socially isolated. Developing support networks may help reduce stress and therefore reduce abuse. Community contacts vary for each abuser and survivor but might include crisis hotlines, support groups, and education classes.

Nurses may also make home visits. Home visits provide support to families and provide them with knowledge about stress and management. Abuse of any kind creates a volatile situation, so nurses may be putting themselves or the survivor in danger if they do make home visits. Carefully assess this possibility before proceeding. If necessary, arrange a safe place to meet the survivor instead.

Evaluation and Treatment Outcomes

Evaluation and outcome criteria depend on the setting for interventions. For instance, if a survivor is encountered in the emergency department, successful outcomes might be that injuries are appropriately managed and the patient's immediate safety is ensured. For long-term care, outcome criteria and evaluation might center on ending abusive relationships. Examples of other outcome criteria that would indicate successful nursing interventions are recognizing that one is not to blame for the violence, demonstrating knowledge of strengths and coping skills, and reestablishing social networks.

Evaluation of nursing care for abused children depends on attaining goals mutually set with the parents or guardians. An end to all violence is the optimal outcome criterion; however, attainment of smaller goals indicates progress toward that end. Outcomes such as increased problem-solving and communication skills within the family, increased self-esteem in both children and parents, and increased use of nonphysical forms of discipline may all indicate progress toward the total elimination of child abuse.

Follow-up efforts are important in evaluating the outcomes of elder abuse. The optimal outcome is to end all abuse and keep the older adults in their own living environment, if appropriate. Although the abuse may have been resolved temporarily, it may flare up again. Ongoing support for the caregiver and assistance with caregiving tasks may be necessary if the older adult is to remain at home. Nursing home or assisted living may be the only desirable option if the burden is too great for the family and the likelihood of ongoing abuse or neglect is high.

Another important outcome of nursing intervention with survivors is

appropriate treatment of any disorder resulting from abuse (e.g., acute stress disorder, PTSD, anxiety disorders, dissociative identity disorder [DID], major depression, substance abuse). Follow-up nursing assessments should monitor symptom reduction or exacerbation, adherence to any medication regimen, and side effects of medication. The ultimate outcome is to end violence and enable the survivor to return to a more productive, safe, and nurturing life without being continually haunted by memories of the abuse.

Nurses must become accustomed to measuring gains in small steps when working with survivors. Making any changes in significant relationships has serious consequences and can be done only when the adult survivor is ready. It is easy to become angry or discouraged with survivors, so it is important not to communicate such feelings. Discussing such feelings with other staff provides a way of dealing with them appropriately. In such discussions with supervisors or other staff, it is imperative to protect the survivor's confidentiality by discussing feelings around issues, not particular individuals, in order to ensure that survivors cannot be identified.

TREATMENT FOR THE ABUSER

Participants in programs that treat abusers are usually present only because the court has mandated the treatment. Programs are often outpatient groups that meet weekly for an extended period, often 36 to 48 weeks. Some programs advocate longer programs, believing that chronic offenders require from 1 to 5 years of treatment to change abusive behavior. States vary on requiring that treatment programs for abusers contact partners.

Interventions must be culturally sensitive. Many factors can affect violence against others, including socioeconomic status, racial or ethnic identity, country of origin, and sexual orientation; those differences must be addressed. When applicable, intervention programs may require abusers to undergo substance abuse treatment concurrently, so patients are required to remain sober and to submit to random drug testing.

SUMMARY OF KEY POINTS

- The most common type of abuse results from domestic violence.
- IPV is a significant public health problem; it includes physical violence, sexual violence, stalking, and psychological aggression.
- IPV crosses all ethnic, racial, and socioeconomic lines. Women are more likely to be injured or killed by current or former intimate partners than by any other perpetrators.
- Stalking is repeated unwanted contact, attention, and harassment that increase in frequency.
- Child maltreatment includes child abuse (i.e., overt actions that cause harm, potential or threat of harm) and child neglect (i.e., failure to provide needs or to protect from harm or potential harm).
- Older adults may also be physically, emotionally, and sexually abused or neglected. The most common type of elder abuse is economic.
- Among the many theories that have been proposed to explain violence are neurologic problems, psychopathology, alcohol and other drug abuse, intergenerational transmission of violence, and economic and community factors
- A well-documented cycle of violence consists of three phases of increasing frequency and severity.
- Nurses need to be familiar with signs and symptoms of abuse and to be vigilant when assessing patients.
- Nurses need to be nonjudgmental when caring for a victim of abuse. Many reasons a person could cause a person to remain in an abusive situation.
- Nursing interventions include physical health interventions and psychosocial interventions that focus on helping victims identify their strengths and validating thoughts and feelings.

Unfolding Patient Stories:Sandra Littlefield

Part 2

Recall from [Chapter 2](#) Sandra Littlefield with borderline personality disorder. She has a history of

unstable relationships, several divorces, prostitution, poor impulse control, drug and alcohol abuse, anxiety, cutting, and suicide attempts. The nurse ascertains that she was sexually abused as a child. What factors in her history are suggestive of abuse? Describe areas of a psychosocial assessment associated with her behaviors. What nursing interventions and education can help promote her mental health stability?

CRITICAL THINKING CHALLENGES

1. Abuse is a pervasive problem, in which anyone can be a victim (e.g., women, men, children, older adults, gays, lesbians). Why do so few nursing units and nurses make it routine to ask questions about abuse?
2. Abuse is not just a “women’s issue”. The prevalence of abuse might decrease if men make it a “men’s issue” as well. What is preventing this from happening?
3. What are your thoughts and feelings about women who are victims of violence in which both partners (victim and perpetrator) abuse alcohol and other drugs?
4. What are your thoughts and feelings about women who will not leave an abusive relationship?
5. What are some reasons that people remain in abusive relationships?
6. Why do some survivors become involved in more than one abusive relationship?
7. How do you handle your feelings toward abusive parents or relatives who abuse older adults?
8. What are the issues in mandatory reporting of violence toward women, particularly violence?
9. Would your thoughts, feelings, and ability to intervene change if the violent relationship is between same-sex partners?

Movie Viewing Guides

Once Were Warriors: 1994. A mother of 5 children reevaluates her 18-year marriage to her alcoholic, hot-tempered husband when his barroom violence tragically encroaches into their home life. Produced and filmed in New Zealand, this film also presents how urbanization has undermined the culture and strength of the indigenous Maori people.

VIEWING POINTS: What evidence can you find in this film that may reflect intergenerational transmission of violence? In what ways do you think that culture can influence attitudes toward abuse (both positive and negative)? What are positive and negative cultural influences in this film?

Sybil: 1976. Sally Field plays Sybil, a woman who experiences DID after suffering horrible abuse during childhood. Help from a psychiatrist (Joanne Woodward) uncovers the memories that have led to the splitting of Sybil's personality. The movie contains harrowing scenes of the abuse Sybil experienced.

VIEW INTS: What symptoms does Sybil show in the film? How does the psychiatrist work with Sybil's different personalities in this film?

Enough: 2002. Jennifer Lopez stars as a blue-collar beauty (Slim Hiller) who marries the really wrong guy. Eventually, she discovers his philandering and spends the rest of the movie in a nomadic flight from his hot-tempered brutality. Bankrolled by her estranged father, she protects her young daughter. Knowing she must face the inevitable showdown, she turns to self-defense courses for empowerment.

VIEWING POINTS: When did Slim and Mitch's relationship turn destructive? What are the characteristics of an abused partner displayed by Slim? What were Mitch Hiller's primary motives in stalking Slim?

Unit VI: **Care and Recovery for Persons with Mental Disorders**

24

Schizophrenia and Related Disorders

Nursing Care of Persons with Thought Disorders

Andrea C. Bostrom

KEYCONCEPTS

- disorganized symptoms
- delusions
- hallucinations
- negative symptoms
- neurocognitive symptoms
- positive symptoms
- psychosis

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Identify key symptoms of schizophrenia.
2. Analyze theories relevant to schizophrenia.
3. Develop strategies to establish a patient-centered, recovery-oriented therapeutic relationship with a person with schizophrenia.
4. Apply a person-centered, recovery-oriented nursing process for patients with schizophrenia.
5. Identify medications used to treat people with schizophrenia and evaluate their effectiveness.
6. Identify and evaluate expected outcomes of nursing care for persons with schizophrenia.
7. Develop wellness strategies for persons with schizophrenia.
8. Differentiate the type of mental health care provided in emergency care, inpatient-focused care, community care, and virtual mental health care.
9. Discuss the importance of integrated health care.
10. Discuss other common schizophrenia spectrum disorders.

KEY TERMS

- Affective lability
- Aggression
- Agitation
- Agranulocytosis
- Akathisia
- Alogia

- Ambivalence

Case Study

Arnold, a 53-year-old man who was diagnosed with paranoid schizophrenia at an early age, had been living on the family farm for the last 30 years with his mother. After his mother's death, the farm was to be sold and divided among the siblings, who arranged for Arnold to move to town. Arnold became agitated and threatening and refused to believe that his parents had died and that he would have to leave the farm.

INTRODUCTION

These fascinating schizophrenia spectrum disorders have confounded scientists and philosophers for centuries. Schizophrenia spectrum disorders are among the most severe mental illnesses; they are found in all cultures, races, and socioeconomic groups. Their symptoms have been attributed to possession by demons, considered punishment by gods for evils done, or accepted as evidence of the inhumanity of its sufferers. These explanations have resulted in enduring stigma for people diagnosed with these disorders. Today, the stigma persists, although it has less to do with demonic possession than with society's unwillingness to shoulder the costs associated with housing, treatment, and rehabilitation. All nurses need to understand these disorders.

SCHIZOPHRENIA SPECTRUM DISORDERS

OVERVIEW

The schizophrenia spectrum disorders include schizophrenia, schizoaffective, delusional and schizotypal disorders, brief psychotic disorder, schizophreniform disorder, and substance-medication-induced psychotic disorder (American Psychiatric Association [APA], 2013). Schizophrenia is the highlighted disorder in this chapter because it has a broad range of symptoms that are found in other schizophrenia spectrum disorders. A discussion of other disorders follows the content on schizophrenia. Schizotypal disorders will be discussed in Chapter 30.

Central to understanding the problems of persons with schizophrenia spectrum disorders is the concept of **psychosis**, a term used to describe a state in which an individual experiences positive symptoms of schizophrenia, also known as psychotic symptoms (e.g., **hallucinations**; **delusions**; disorganized thoughts, speech, or behavior).

KEYCONCEPT Psychosis, a state in which a person experiences hallucinations, delusions, or disorganized thoughts, speech, or behavior, is the key diagnostic factor in schizophrenia spectrum disorders.

SCHIZOPHRENIA

In the late 1800s, Emil Kraepelin first described the course of the disorder he called *dementia praecox* because of its early onset and notable changes in an individual's cognitive functioning. In the early 1900s, Eugen Bleuler renamed the disorder *schizophrenia*, meaning *split minds*, and began to determine that there was not just one type of schizophrenia but rather a group of schizophrenias. More recently, Kurt Schneider differentiated behaviors associated with schizophrenia as “first rank” symptoms (e.g., psychotic delusions, hallucinations) and “second rank” symptoms (i.e., all other experiences and behaviors associated with the disorder). These pioneering physicians had a great influence on the current diagnostic conceptualizations of schizophrenia that emphasize the heterogeneity of the disorder in terms of symptoms, course of illness, and positive and negative symptoms.

Clinical Course

Schizophrenia robs people of mental health and imposes social stigma. People with schizophrenia struggle to maintain control of their symptoms, which affect every aspect of their lives. The person with schizophrenia displays various interrelated symptoms and experiences and cognitive deficits in several areas.

Because schizophrenia is a disorder of thoughts, perceptions, and behavior, it is sometimes not recognized as an illness by the person experiencing the symptoms. Many people with thought disorders do not believe that they have a mental illness. Their denial of mental illness and the need for treatment poses problems for the family and clinicians. Ideally, in lucid moments, patients recognize that their thoughts are really delusions, that their perceptions are hallucinations, and that their behavior is disorganized. In reality, many patients do not believe that they have a mental illness but agree to treatment to please family and clinicians.

The natural progression of schizophrenia is usually described as a chronic illness that deteriorates over time and with an eventual plateau in the symptoms. Only for older adults with schizophrenia has it been suggested that improvement might occur. In reality, no one really knows what the course of schizophrenia would be if patients were able to adhere to a treatment regimen throughout their lives. Only recently have medications become relatively effective, with manageable side effects. The clinical picture of schizophrenia is complex; individuals differ from one another, and the experience for a single individual may vary from episode to episode.

Prodromal Period

A **prodromal period** (stage of early changes that are a precursor to the disorder) may begin in early childhood. More than half of patients report the following **prodromal** symptoms: tension and nervousness, lack of interest in eating, difficulty concentrating, disturbed sleep, decreased enjoyment and loss of interest, restlessness, forgetfulness, depression, social withdrawal from friends, feeling laughed at, more thinking about religion, feeling bad for no reason, feeling too excited, and hearing voices or seeing things (Jaaro-Peled & Sawa, 2020; Liu et al., 2019a). The benefit of discovering the presence of symptoms

early, before they have solidified into a major disorder, is that treatment might be initiated earlier.

Acute Illness

Initially, the behaviors of this illness may be both confusing and frightening to the individual and the family. The symptoms of acute illness usually occur in late adolescence or early adulthood. The behaviors may be subtle; however, at some point they become so disruptive or bizarre that they can no longer be overlooked. These might include episodes of staying up all night for several nights, incoherent conversations, or aggressive acts against oneself or others. For example, one patient's parents reported their son walking around the apartment for several days holding his arms and hands as if they were a machine gun, pointing them at his parents and siblings, and saying "rat-a-tat-tat, you're dead." Another father described his son's first delusional-hallucinatory episode as so convincing that it was frightening. His son began visiting cemeteries and making "mind contact" with the deceased. He saw his deceased grandmother walking around in the home and was certain that pipe bombs were hidden in objects in his home.

As symptoms worsen, patients are less and less able to care for their basic needs (e.g., eating, sleeping, bathing). Substance use is common. Functioning at school or work deteriorates. Dependence on family and friends increases, so those individuals recognize the patients' need for treatment. In the acute phase, individuals afflicted by schizophrenia are at high risk for suicide. Patients may be hospitalized to protect themselves or others.

Initial treatment focuses on alleviation of symptoms through beginning therapy with medications, decreasing the risk of suicide through safety measures, normalizing sleep, and reducing substance use. Functional deficits persist during this period, so the patient and family must begin to learn to cope with these deficits. Emotional blunting diminishes the ability and desire to engage in hobbies, vocational activities, and relationships. Limited participation in social activities spirals into numerous skill deficits, such as difficulty engaging others interpersonally. Cognitive deficits lead to problems recognizing patterns in situations and transferring learning and behaviors from one circumstance to a similar one.

Stabilization

After the initial diagnosis of schizophrenia and initiation of treatment, stabilization of symptoms becomes the focus. Symptoms become less acute but may still be present. Treatment is intense during this period as medication regimens are established, and patients and their families begin to adjust to the idea of a family member having a long-term severe mental illness. Ideally, the use of substances is eliminated. Socialization with others begins to increase, so that rehabilitation begins.

Recovery

The ultimate goal is recovery. For individuals with a severe mental illness like schizophrenia, this will entail learning to live as well as possible with the illness and its symptoms (Cripps & Hood, 2020). Medication generally diminishes the symptoms and allows the person to work toward recovery. However, no medication will cure schizophrenia. As with any chronic illness, following a therapeutic regime will help the individual to live as well as possible with the illness. Living well with schizophrenia requires the patient, family, and providers to work toward acceptance of the illness while offering hope for the best possible outcomes, encouraging autonomy with personal and reasonable goal setting, decreasing self-stigma while creating a positive self-image, finding ways to extract pleasure from life, and creating and maintaining social connections with families and peers (Cripps & Hood, 2020). This can be partially obtained by maintaining a healthy lifestyle, managing the stresses of life, and developing meaningful interpersonal relationships. Family support and involvement are extremely important at this time. After the initial diagnosis has been made, patients and families must be educated to anticipate and expect relapse and know how to cope with it.

Relapses

Relapses can occur at any time during treatment and recovery. They are very

detrimental to the successful management of this disorder. Relapse is not inevitable; however, it occurs with sufficient regularity to be a major concern in the treatment of schizophrenia. With each relapse, a longer period of time is needed to recover. Combining medications and psychosocial treatment greatly diminishes the severity and frequency of recurrent relapses (Ceraso et al., 2020; Lauriello & Perkins, 2019).

One major reason for relapse is failure to take medication consistently. Even with newer medications, adherence continues to be a challenge (Chang et al., 2019). Discontinuing medications will almost certainly lead to a relapse (Dufort & Zipursky, 2019). Lower relapse rates are found, for the most part, among groups who carefully follow a treatment regimen.

Many other factors trigger relapse. Impairment in cognition and coping leaves patients vulnerable to stressors. Limited accessibility of community resources, such as public transportation, housing, entry-level and low-stress employment, and limited social services, leaves individuals without access to social support. Income supports that can buffer the day-to-day stressors of living may be inadequate. The degree of stigmatization that the community holds for mental illness attacks the self-concept of patients. Social isolation and the level of responsiveness from family members, friends, and supportive others (e.g., peers and professionals) when patients need assistance also have an impact.

Consider Arnold

Recall that Arnold's relapse was triggered by his mother's death and being forced to leave the family farm.

Diagnostic Criteria

Schizophrenia is characterized by positive and negative symptoms that are present for a significant portion of a 1-month period but with continuous signs of disturbance persisting for at least 6 months (APA, 2013). We define **positive symptoms** as hallucinations and delusions and **negative symptoms** as diminished emotional expression and **avolition** (lack of interest or motivation in goal-directed behavior, such as getting dressed and going to work or school). See

Positive Symptoms of Schizophrenia

Positive symptoms can be thought of as excessive or distorted thoughts and perceptions that occur within the individual but are not experienced by others. Hallucinations and delusions are positive symptoms of schizophrenia. An easy way to remember the difference between hallucinations and delusions is that hallucinations involve one or more of the five senses. Delusions involve only thoughts.

A fairly common hallucination is a command hallucination, that is, an auditory hallucination instructing the patient to act in a certain way, because voices are telling the person to do something. **Command hallucinations** range from innocuous (eat all of your dinner) to very serious (hurt someone or jump in front of a bus).

KEYCONCEPT Positive symptoms reflect an excess or distortion of normal functions, including delusions and hallucinations (APA, 2013).

KEYCONCEPT Hallucinations are perceptual experiences that occur without actual external sensory stimuli. They can involve any of the five senses, but they are usually *visual* or *auditory*. Auditory hallucinations are more common than visual ones. For example, the patient may hear voices carrying on a discussion about their own thoughts or behaviors.

KEYCONCEPT Delusions are erroneous, fixed, false beliefs that cannot be changed by reasonable argument. They usually involve a misinterpretation of experience. For example, the patient believes someone is reading their thoughts or plotting against them. Various types of delusions include the following:

- *Grandiose*: the belief that one has exceptional powers, wealth, skill, influence, or destiny
- *Nihilistic*: the belief that one is dead or a calamity is impending
- *Persecutory*: the belief that one is being watched, ridiculed, harmed, or plotted against
- *Somatic*: beliefs about abnormalities in bodily functions or structures

Negative Symptoms of Schizophrenia

The term *negative symptoms* is used to describe emotions and behaviors that should be present but are diminished in persons with schizophrenia. Negative symptoms are not as dramatic as positive symptoms, but they can interfere greatly with the patient's ability to function day to day. Because expressing emotion is difficult for them, people with schizophrenia laugh, cry, and get angry less often. Their affect is flat; they show little or no emotion when personal loss occurs. They also experience **ambivalence**, which is the concurrent experience of equally strong opposing feelings so that it is impossible to make a decision. Avolition may be so profound that simple activities of daily living (ADLs), such as dressing or combing hair, may not get done. **Anhedonia** prevents the person with schizophrenia from enjoying activities. People with schizophrenia may have limited speech and difficulty saying anything new or carrying on a conversation. These negative symptoms cause the person with schizophrenia to withdraw and experience feelings of severe isolation.

KEY CHARACTERISTICS 24.1 • SCHIZOPHRENIA

Diagnostic Criteria

- A. Two (or more) of the following, each present for a significant portion of time during a 1-month period (or less if successfully treated). At least one of these must be (1), (2), or (3):
 - 1. Delusions
 - 2. Hallucinations
 - 3. Disorganized speech (e.g., frequent derailment or incoherence)
 - 4. Grossly disorganized or catatonic behavior
 - 5. Negative symptoms (i.e., diminished emotional expression or avolition)
- B. For a significant portion of the time since the onset of the disturbance, level of functioning in one or more major areas, such as work, interpersonal relations, or self-care, is markedly below the level achieved prior to the onset (or when the onset is in childhood or adolescence, there is failure to achieve expected level of interpersonal, academic, or occupational functioning).
- C. Continuous signs of the disturbance persist for at least 6 months. This 6-month period must include at least 1 month of symptoms

(or less if successfully treated) that meet Criterion A (i.e., active-phase symptoms) and may include periods of prodromal or residual symptoms. During these prodromal or residual periods, the signs of the disturbance may be manifested by only negative symptoms or by two or more symptoms listed in Criterion A present in an attenuated form (e.g., odd beliefs and unusual perceptual experiences).

- D. SAD and depressive or bipolar disorder with psychotic features have been ruled out because either (1) no major depressive or manic episodes have occurred concurrently with the active-phase symptoms or (2) if mood episodes have occurred during active-phase symptoms, they have been present for a minority of the total duration of the active and residual periods of the illness.
- E. The disturbance is not attributable to the physiological effects of a substance (e.g., a drug of abuse, a medication) or another medical condition.
- F. If there is a history of autism spectrum disorder or a communication disorder of childhood onset, the additional diagnosis of schizophrenia is made only if prominent delusions or hallucinations, in addition to the other required symptoms of schizophrenia, are also present for at least 1 month (or less if successfully treated).

Target Symptoms and Associated Findings

- Inappropriate affect
- Loss of interest or pleasure
- Dysphoric mood (anger, anxiety, or depression)
- Disturbed sleep patterns
- Lack of interest in eating or refusal of food
- Difficulty concentrating
- Some cognitive dysfunctions, such as confusion, disorientation, or memory impairment
- Lack of insight
- Depersonalization, derealization, and somatic concerns
- Motor abnormalities

Associated Physical Examination Findings

- Physically awkward
- Poor coordination or mirroring
- Motor abnormalities
- Cigarette-related pathologies, such as emphysema and other pulmonary and cardiac problems

Associated Laboratory Findings

- Enlarged ventricular system and prominent sulci in the brain cortex
- Decreased temporal and hippocampal size
- Increased size of basal ganglia
- Decreased cerebral size
- Slowed reaction times
- Abnormalities in eye tracking

KEYCONCEPT Negative symptoms reflect a lessening or loss of normal functions, such as restriction or flattening in the range and intensity of emotion (diminished emotional expression), reduced fluency and productivity of thought and speech (**alogia**), withdrawal and inability to initiate and persist in goal-directed activity (avolition), and inability to experience pleasure (anhedonia).

Neurocognitive Impairment

Neurocognitive impairment exists in people with schizophrenia and may be independent of positive and negative symptoms. Neurocognition includes memory (short- and long-term); vigilance or sustained attention; verbal fluency or the ability to generate new words; and executive functioning, which includes volition, planning, purposeful action, and self-monitoring behavior. Working memory is a concept that includes short-term memory and the ability to store and process information.

KEYCONCEPT Neurocognitive impairment in memory, vigilance, and executive functioning is related to poor functional outcomes in schizophrenia.

This impairment is independent of the positive symptoms. That is, cognitive dysfunction can exist even if the positive symptoms are in remission. Not all areas of cognitive functioning are impaired. Long-term memory and intellectual functioning are not necessarily affected. However, low intellectual functioning is

common and may be related to a lack of educational experiences and opportunities due to the age of illness onset. Neurocognitive dysfunction is often manifested in disorganized symptoms (Vignapiano et al., 2019).

KEYCONCEPT **Disorganized symptoms** of schizophrenia are findings that make it difficult for the person to understand and respond to the ordinary sights and sounds of daily living. These include **confused speech and thinking**, and disorganized behavior.

Disorganized Thinking

The following are examples of confused speech and thinking patterns:

- **Echolalia**—repetition of another’s words that is parrot-like and inappropriate
- **Circumstantiality**—extremely detailed and lengthy discourse about a topic
- **Loose associations**—absence of the normal connectedness of thoughts, ideas, and topics; sudden shifts without apparent relationship to preceding topics
- **Tangentiality**—the topic of conversation is changed to an entirely different topic that is a logical progression but causes a permanent detour from the original focus
- **Flight of ideas**—the topic of conversation changes repeatedly and rapidly, generally after just one sentence or phrase
- **Word salad**—stringing together words that are not connected in any way
- **Neologisms**—words that are made up that have no common meaning and are not recognizable
- **Paranoia**—suspiciousness and guardedness that are unrealistic and often accompanied by grandiosity
- **Referential thinking**—a belief that neutral stimuli have special meaning to the individual, such as a television commentator who is speaking directly to the individual
- **Autistic thinking**—restricts thinking to the literal and immediate so that the individual has private rules of logic and reasoning that make no sense to anyone else
- **Concrete thinking**—lack of abstraction in thinking; inability to understand punch lines, metaphors, and analogies
- **Verbigeration**—purposeless repetition of words or phrases
- **Metonymic speech**—use of words with similar meanings interchangeably
- **Clang association**—repetition of words or phrases that are similar in sound but in no other way, for example, “right, light, sight, might”

- **Stilted language**—overly and inappropriately artificial formal language
- **Pressured speech**—speaking as if the words are being forced out

Disorganized perceptions often create oversensitivity to colors, shapes, and background activities. **Illusions** occur when the person misperceives or exaggerates stimuli that actually exist in the external environment. This is in contrast to hallucinations, which are perceptions in the absence of environmental stimuli. Ancillary symptoms that may accompany schizophrenia include anxiety, depression, and hostility.

Disorganized Behavior

Disorganized behavior (which may manifest as very slow, rhythmic, or ritualistic movement), coupled with disorganized speech, makes it difficult for the person to partake in daily activities. Examples of disorganized behavior include the following:

- **Aggression**—behaviors or attitudes that reflect rage, hostility, and the potential for physical or verbal destructiveness (usually comes about if the person believes someone is going to do them harm)
- **Agitation**—inability to sit still or attend to others, accompanied by heightened emotions and tension
- **Catatonia**—psychomotor disturbances, such as stupor, mutism, posturing, or repetitive behavior
- **Catatonic excitement**—a hyperactivity characterized by purposeless activity and abnormal movements, such as grimacing and posturing
- **Echopraxia**—involuntary imitation of another person's movements and gestures
- **Regressed behavior**—behaving in a manner of a less mature life stage; childlike and immature behavior
- **Stereotypy**—repetitive purposeless movements that are idiosyncratic to the individual and to some degree outside of the individual's control
- **Hypervigilance**—sustained attention to external stimuli as if expecting something important or frightening to happen
- **Waxy flexibility**—posture held in an odd or unusual fixed position for extended periods of time

Disruption in Sense of Self

Many of the symptoms observed in schizophrenia may be attributable to brain deficiencies that affect the individual's experience of "self". The self is difficult to define but is often used to describe who we are: self-concept, self-consciousness, self-awareness, and, for people with schizophrenia, self-disturbance. This self-disturbance leads to significant difficulty determining what thoughts and experiences are internal versus external to the individual. Delusions and hallucinations can be explained by this, as can the person's failures of insight, self-awareness, and self-monitoring (Klaunig et al., 2019). Self-disturbance also suggests ways that adolescents and young adults may be identified during the prodromal period of the illness by their difficulties in integrating self-experiences. Treatment that focuses on self-disturbance aims to help clients to become active agents in their own care. This can be done by helping them to develop concepts of themselves in the world and creating narratives of how their experiences have developed and can be managed in the future in their own unique way (Lysaker & Roe, 2016). Treatment that helps to develop a sense of "self" is possible and integral to recovery (Davidson, 2019).

Schizophrenia Across the Life-Span

Children

The diagnosis of schizophrenia is rare in children before adolescence. When it does occur in children aged 5 or 6 years, the symptoms are essentially the same as in adults. In this age group, hallucinations tend to be visual, and delusions less developed. Because disorganized speech and behavior may be explained better by other disorders that are more common in childhood, those disorders should be considered before applying the diagnosis of schizophrenia to a child.

However, new studies suggest that the likelihood of children later experiencing schizophrenia can be predicted. Developmental abnormalities in childhood, including delays in attainment of speech and motor development, problems in social adjustment, and poorer academic and cognitive performance, have been found to be present in individuals who experience schizophrenia in adulthood. Adults who had childhood cognitive, social, behavioral, and emotional impairments may be at higher risk of developing schizophrenia (Jaaro-Peled & Sawa, 2020).

Older Adults

People with schizophrenia usually get older, and some people develop schizophrenia in late life. For older patients who have had schizophrenia since young adulthood, this may be a time in which they experience some improvement in symptoms or decrease in relapse fluctuations. There is some evidence that suggests that older adults with schizophrenia may be more likely to develop cognitive impairment than those without mental disorders (Shahab et al., 2019). However, their lifestyle is probably dependent on the effectiveness of earlier treatment, the support systems that are in place (including relationships with family members and professionals), and the interaction between environmental stressors and the patient's functional impairments. The cost of caring for older patients with schizophrenia remains high because many are no longer cared for in institutions and because community-based treatment has developed more slowly for this age group than for younger adults.

Epidemiology and Risk Factors

Schizophrenia is found in all cultures and countries. It is prevalent in about 0.48% of the worldwide population (ranging from 0.34% to 0.85%) and is listed within the top 20 illnesses for life lost resulting from premature death and years lived in less than full health (Lin et al., 2018). Its economic costs are enormous. Direct costs include treatment expenses; indirect costs include lost wages, premature death, and involuntary commitment. In addition, employment among people with schizophrenia is one of the lowest of any group with disabilities. The costs of schizophrenia in terms of individual and family suffering are probably inestimable.

People with schizophrenia tend to cluster in the lowest social classes in industrialized countries and urban communities. The symptoms of the illness are so pervasive that it is difficult for these individuals to maintain any type of gainful employment. Homelessness is a problem for people with severe mental illness (e.g., schizophrenia or bipolar illness). People with schizophrenia are more likely to remain homeless with few opportunities for employment (Glick & Olfson, 2018; Wu et al., 2018).

Internal and External Risk Factors

Genetic factors related to cognitive and brain function and brain structure are known risks for schizophrenia. Early neurologic problems, stressful life events, and nonhereditary genetic factors also contribute to the likelihood of developing the disorder. Environmental factors related to schizophrenia include migrant status, having an older father, *Toxoplasma gondii* antibodies, prenatal famine, lifetime cannabis use, obstetric complications, urban rearing, and winter or spring birth (Abrahamyan Empson et al., 2020; Hollander et al., 2020).

Age of Onset

Schizophrenia is usually diagnosed in late adolescence and early adulthood. Men tend to be diagnosed between the ages of 18 and 25 years and women between the ages of 25 and 35 years. The earlier the diagnosis and the longer the psychosis remains untreated, the more severe the disorder becomes (Shahab et al., 2019). Conversely, the earlier the psychosis is recognized and treated within an evidence-based comprehensive program, the better the outcomes (Dixon et al., 2018).

Gender Differences

Men tend to be diagnosed earlier and have a poorer prognosis than women. This may be a sex-linked outcome, but it may also reflect the poorer prognosis for any individual who develops the disorder at an early age (Lewine et al., 2017). When women are diagnosed early, they are at higher risk for physical comorbidities than men (Šimunović Filipčić et al., 2020).

Ethnicity and Culture

Increasingly, efforts are being made to consider culture and ethnic origin when diagnosing and treating individuals with schizophrenia. Racial groups may have

varying diagnostic rates of schizophrenia. However, it is not clear whether these findings represent correct diagnosis or misdiagnosis of the disorder based on the cultural bias of the clinician. For instance, schizophrenia has been consistently overdiagnosed among African Americans. African American and Latinx individuals with bipolar disorder are more likely to have misdiagnoses of schizophrenia than are White individuals. Serious mental disorders may remain unrecognized in Asian Americans because of stereotypical beliefs that they are “problem free” (Maura et al., 2017).

Familial Differences

First-degree biologic relatives (e.g., children, siblings, parents) of an individual with schizophrenia have a 10 times estimated greater risk for schizophrenia than the general population. Other relatives may have an increased risk for related disorders, such as schizoaffective disorder (SAD) and schizotypal personality disorder (Hilker et al., 2018).

Comorbidity

Several somatic and psychological disorders coexist with schizophrenia. This results in significant morbidity and mortality for people with schizophrenia, with individuals who have this diagnosis dying up to 20 years earlier than the general population. Physical health conditions and illnesses to which people with schizophrenia are particularly susceptible include tuberculosis, human immunodeficiency disease, hepatitis B and C, osteoporosis, poor dentition, impaired lung function, altered (reduced) pain sensitivity, sexual dysfunction, obstetric complications, cardiovascular problems, hyperpigmentation, obesity, diabetes mellitus (DM), metabolic syndrome with hyperlipidemia, polydipsia, thyroid dysfunction, and hyperprolactinemia (Kessler & Lev-Ran, 2019; Postolache et al., 2019). Early mortality may be from natural causes (cardiovascular, cancer, chronic obstructive pulmonary disease, DM, and influenza and pneumonia) or unnatural causes (suicide, substance and alcohol abuse, and legal interventions) (Lin et al., 2018). Several health system factors contribute to this, including barriers to obtaining primary care and the primary care providers’ lack of preparation and discomfort addressing mental health

issues and conditions, the insufficient preparation of mental health practitioners in managing physical illness, the tendency for mental health providers to fail to ask about physical health, and the absence of standards of care that include screening and monitoring medical issues.

The coronavirus disease 2019 pandemic is significantly impacting persons with schizophrenia. Their symptoms, such as delusions, hallucinations, disorganized behavior, cognitive impairment, and poor insight, make it harder for adequate infection control. Many people with schizophrenia live in congregate housing, which compounds the likelihood of infection. Treatment options are less accessible because of the pandemic restrictions related to inpatient and outpatient care (Kozloff et al., 2020).

Substance Abuse and Depression

Among the behavioral comorbidities, substance use is common. Depression may also be observed in patients with schizophrenia. This is an important symptom for several reasons. First, depression may be evidence that the diagnosis of a mood disorder is more appropriate. Second, depression is not unusual in chronic stages of schizophrenia and deserves attention. Third, 50% of people with schizophrenia attempt suicide, and 10% to 15% die by suicide. Risk factors for suicide are untreated psychosis, history of suicide attempt, age younger than 28 years, severity of depression, and substance abuse (Kim et al., 2019; Naguy & Al-Rabaie, 2017).

Diabetes Mellitus and Obesity

Interest has been renewed in the relationship between DM and schizophrenia. Years ago, an association was established between glucose regulation and psychiatric disorders, suggesting that people with schizophrenia may be more prone to type II DM than the general public (Franzen, 1970; Schimmelbusch et al., 1971). Evidence that supports this view includes a higher rate of type II diabetes in first-degree relatives of people with schizophrenia and higher rates of impaired glucose tolerance and insulin resistance among people with schizophrenia. However, obesity, which is associated with type II diabetes, is a

growing problem in the United States, in general, and is complicated in schizophrenia treatment by the tendency of individuals to gain weight after their disease is managed with medications. Weight gain in some individuals may be attributed to a return to a healthier living situation, in which regular meals are available and symptoms that interfere with obtaining food regularly (e.g., delusions) are decreased. For others, weight gain may be a medication side effect (Kowalchuk et al., 2019).

Etiology

Schizophrenia is believed to be caused by the interaction of a biologic predisposition or vulnerability and environmental stressors (see the diathesis-stress model discussed in [Chapter 13](#)). See [Box 24.1](#) for deficits related to vulnerability in schizophrenia. Environmental stressors include pregnancy or obstetric complications and social adversity, such as migration, unemployment, urban living, childhood abuse, and social isolation or absence of close friends (Hollander et al., 2020).

Biologic Theories

Neuroanatomic Findings

The lateral and third ventricles are somewhat larger, and total brain volume is somewhat less in persons with schizophrenia compared with those without schizophrenia. The thalamus and the medial temporal lobe structures, including the hippocampus, and superior temporal and prefrontal cortices, tend to be smaller also (Dietsche et al., 2017; Wang et al., 2019).

BOX 24.1

Deficits that Cause Vulnerability in Schizophrenia

COGNITIVE DEFICITS

- Deficits in processing complex information

- Deficits in maintaining a steady focus of attention
- Inability to distinguish between relevant and irrelevant stimuli
- Difficulty forming consistent abstractions
- Impaired memory

PSYCHOPHYSIOLOGIC DEFICITS

- Deficits in sensory inhibition
- Poor control of autonomic responsiveness

SOCIAL SKILLS DEFICITS

- Impairments in processing interpersonal stimuli, such as eye contact or assertiveness
- Deficits in conversational capacity
- Deficits in initiating activities
- Deficits in experiencing pleasure

COPING SKILLS DEFICITS

- Overassessment of threat
- Underassessment of personal resources
- Overuse of denial

Genetic Associations

Genetic associations have been identified in a number of regions of the brain, and some have already been tied to neuropathways related to cognitive deficits. The future of treatment of schizophrenia will rely heavily on the outcome of ongoing research (Toulopoulou et al., 2019).

Neurodevelopment

The neurodevelopmental hypothesis explains the etiology of schizophrenia as pathologic processes caused by genetic and environmental factors that begin before the brain reaches its adult state. Evidence suggests that in utero during the first or second trimester, genes involved with cell migration, cell proliferation, axonal outgrowth, and myelination may be affected by neurologic insults, such as viral infections. That is, early neurodevelopmental insults may lead to dysfunction of specific networks that become obvious at adolescence during the normal loss of some plasticity and synapse development (La Barbera et al., 2019).

Neurotransmitters, Pathways, and Receptors

Positron emission tomography (PET) scan findings suggest that in schizophrenia, brain metabolism is generally reduced, with a relative hypermetabolism in the left side of the brain and in the left temporal lobe. Abnormalities exist in specific areas of the brain in the frontal, temporal, and cingulate regions. These findings support further exploration of differential brain hemisphere function in people with schizophrenia (Fig. 24.1). Other PET studies show **hypofrontality**, or a reduced cerebral blood flow and glucose metabolism in the prefrontal cortex of people with schizophrenia and hyperactivity in the limbic area (Buchsbaum, 1990; Hazlett et al., 2019) (Figs. 24.2 and 24.3).

Dopamine Dysregulation

A longstanding explanation of the neurobiological symptoms of schizophrenia is the dopamine hypothesis. Because conventional antipsychotics blocked dopamine and treated the positive symptoms of schizophrenia—specifically, hallucinations and delusions—it was reasoned that *hyperactivity* in the mesolimbic tract at the D2 receptor site in the striatal area (where memory and emotion are regulated) was responsible for these symptoms. Conversely, chronic low levels of dopamine in the prefrontal cortex were thought to underlie cognitive dysfunction in schizophrenia.

FIGURE 24-1: Area of abnormal functioning in a person with schizophrenia. These three views show the excessive neuronal activity in the left globus pallidus (portion of the basal ganglia next to the putamen). (Courtesy of John W. Haller, PhD, Departments of Psychiatry and Radiology, Washington University, St. Louis.)

FIGURE 24-2: Metabolic activity in a control subject (*left*), a subject with obsessive-compulsive disorder (*center*), and a subject with schizophrenia (*right*).

(Courtesy of Monte S. Buchsbaum, MD, The Mount Sinai Medical Center and School of Medicine, New York.)

Today, research focuses on several of the molecular links to dopamine synthesis and increased release of dopamine. Dopamine has a role in the pathogenesis of schizophrenia, but it is more complicated than previously thought. Dopamine activity is related to other disorders, cortical functioning, and stress (Abi-Dargham, 2020).

Role of Other Receptors

Other receptors are also involved in dopamine neurotransmission, especially serotonergic receptors. It is becoming clear that schizophrenia does not result from dysregulation of a single neurotransmitter or biogenic amine (e.g., norepinephrine, dopamine, or serotonin). Investigators are also hypothesizing a role for glutamate and gamma-aminobutyric acid (GABA) because of the complex interconnections of neuronal transmission and the complexity and heterogeneity of schizophrenia symptoms. The *N*-methyl-D-aspartate class of glutamate receptors is being studied because of the actions of phencyclidine (PCP) at these sites and because of the similarity of the psychotic behaviors that are produced when someone takes PCP (see [Figs. 24.1–24.3](#)).

Gut Microbiota

Intestinal flora are necessary for brain development and overall health. Gut bacteria are involved in immune regulation and protect the body through the development of mucosal lymphoid tissue. The **gut–brain axis** (the two-way communication system that connects the gut with the brain) is involved with the intestinal microbiome, neuroendocrine (hypothalamus-pituitary-adrenal axis), immune, and nervous systems. The gut microbiota communicates with the central nervous system (CNS) through the vagus nerve. Emerging research is linking the gut microbiota to the development of mental disorders through the gut–brain axis. It is hypothesized that abnormalities in the gut microbiota increase inflammatory cytokines that may cause neuronal damage, cell death, and abnormal brain development (Yuan et al., 2019).

FIGURE 24-3: Positron emission tomography scan with ^{18}F -deoxyglucose shows metabolic activity in a horizontal section of the brain in a control subject (*left*) and in an unmedicated patient with schizophrenia (*right*). Red and yellow indicate areas of high metabolic activity in the cortex; green and blue indicate lower activity in the white matter areas of the brain. The frontal lobe is magnified to show reduced frontal activity in the prefrontal cortex of the patient with schizophrenia. (Courtesy of Monte S. Buchsbaum, MD, The Mount Sinai Medical Center and School of Medicine, New York.)

Psychosocial Theories

Social factors can contribute to the changes in brain function that result in schizophrenia and add to the day-to-day challenges of living with a mental illness. Childhood trauma, living in an urban environment, and being a member of a minority are all associated with psychotic syndromes. They can also create

barriers to obtaining necessary treatment and recovery (Hollander et al., 2020; Mohammadzadeh et al., 2019). One of the major social stressors is the social stigma that surrounds all mental illnesses (see [Chapter 2](#)). The clinical vignette in [Box 24.2](#) describes the impact of living with a stigmatizing illness. Another is the absence of good, affordable, and supportive housing in many communities. With 2010's enactment of insurance parity for mental illness in the Affordable Care Act, it is hoped that quality and continuity of care will be enhanced. Finally, the mental health service delivery system is fragmented; its quality and types of services vary from community to community, based in part on state legislative and mental health department funding differences.

Family Response to Disorder

Initially, families usually experience disbelief, shock, and fear, along with concern for the family member. Families may attribute the episode to taking illicit drugs or to extraordinary stress or fatigue and hope that this is an isolated or transient event. They may be fearful of the behaviors and respond to patient's anger and hostility with fear, confusion, and anxiety. They may deny the severity and chronicity of the illness and only partially engage in treatment. As families begin to acknowledge the disorder and the long-term care nature of recovery, they themselves may feel overwhelmed, angry, and depressed. In many instances, parents become caregivers as the person transitions into adulthood. As caregivers for their adult children, the parents face many challenges accessing health care and resources (Young et al., 2019). See [Box 24.3](#) for discussion of recovery-oriented family interventions.

BOX 24.2 CLINICAL VIGNETTE

Graduate Student in Peril

B.G.W. born in 1993, spent most of his teenage years using drugs and alcohol, behavior that started when he was 11 years old. He and his small group of friends spent their teenage years outside of school riding around on bicycles. He failed 8th grade, repeated it, and made it to 10th grade. He was removed permanently from school at the age of 16 years. His dress included a dirty denim jacket or Army fatigues, torn tee shirts with rock band logos, and tight-fitting jeans. At age 16, he was hospitalized for a psychotic episode initiated by lysergic acid diethylamide (LSD); it was the scariest moment of his life. His mind had been getting fuzzier every day; he had dabbled with black magic and Satanism. Later, he admitted that for

years he had been trapped in a fantasy land, only partially explained by his drug use.

Years of treatment followed; even with abstinence from drugs, his mental status fluctuated. After antipsychotic agents were prescribed, he began to feel like himself. He was motivated to complete his General Education Diploma (GED) and entered college. He kept his mental illness a secret. While in graduate school, his thoughts, feelings, and behaviors began to change. His thinking became delusional, his moods unpredictable, and his behaviors illogical. Finally, he was hospitalized again, and his condition was stabilized with medication. Currently, he is reapplying to graduate school, and this time he vows to keep people close to him aware of his mental status.

What Do You Think?

- What role did stigma play in the treatment process?
- What information should BGW share with his social network about his mental illness and treatment?

Adapted from Graduate student in peril: A first person account of schizophrenia. (2002). *Schizophrenia Bulletin*, 28(4), 745–755.

RECOVERY-ORIENTED CARE FOR PERSONS WITH SCHIZOPHRENIA

Teamwork and Collaboration: Working Toward Recovery

The most effective approach to treatment for individuals with schizophrenia involves various disciplines, including nursing (both generalist and advanced practice psychiatric nurses), psychiatry, psychology, social work, occupational and recreational therapy, and pastoral counseling. Individuals with general education in psychology, sociology, and social work often serve as case managers, nursing aides, technicians, and other support personnel in hospitals and community treatment agencies. Peer counselors are sometimes used in community agencies and offer support and hope for a better future.

Patients need help in accepting and understanding their illness, setting goals, and developing a support system that encourages their recovery. Recovery-oriented strategies can address hopelessness associated with suicide attempts or withdrawal from relationships with others and encourage an independent lifestyle. Medication management is central to the treatment of schizophrenia and is the responsibility of the patient, physicians, nurses, and pharmacists. Psychosocial interventions can be implemented by all members of the mental health team and may include cognitive-behavioral, music, vocational, mindfulness, and support therapies. These varied professionals and paraprofessionals are important because of the complex nature of the symptoms, the long-term nature of the disorder, and the need for health promotion support.

Complementary and alternative therapies, such as yoga, breathing exercises, relaxation, meditation and mindfulness, and aerobic exercise, may be helpful as adjunctive to the usual care.

BOX 24.3

Research for Evidence-Based Practice—Family-Focused Recovery: Perspectives from Individuals with a Mental Illness

Waller, S., Reupert, A., Ward, B., McCormick, F., & Kidd, S. (2019). Family-focused recovery: Perspectives from individuals with a mental illness. *International Journal of Mental Health Nursing*, 28(1), 247–255.

THE QUESTION: How do those with mental illness define *family* and the role of family in their recovery?

METHODS: Purposive sampling and snowballing were used to recruit and conduct semi-structured interviews with 12 people diagnosed with a severe mental illness.

FINDINGS: Participants defined *family* in various ways, with some being very inclusive and others more selective. There was acknowledgment that family contributed to the individual's recovery in myriad ways, although the need for boundaries was stressed.

IMPLICATIONS FOR NURSING: Nurses should recognize that there is not one definition of *family* and that it is important for the patient to define their family.

Safety Issues

Several special concerns exist when working with people with schizophrenia. A suicide assessment should always be completed when a person is experiencing a psychotic episode. In an inpatient unit, patient safety concerns extend to potentially aggressive actions toward staff and other patients during episodes of psychosis. During times of acute illness, a priority of care is treatment with antipsychotic medications and, in some instances, hospitalization.

Nurses should assess the person's risk for suicide because of the high suicide and attempted suicide rates among persons with schizophrenia (see [Chapter 22](#)). One challenge is to distinguish among the displayed behaviors to determine if the person is displaying negative symptoms, side effects of antipsychotic medications, or actual depression and demoralization as a result of this illness. Does the patient speak of suicide, or have delusional thinking that could lead to

dangerous behavior, or have command hallucinations telling them to harm self or others? Does the patient have homicidal ideations? Does the patient lack social support and the skills to be meaningfully engaged with other people or a vocation? Does the patient express feelings of not belonging to a social group or being a burden to loved ones? Substance-related disorders are also common among patients with schizophrenia, so that nurses should assess for substance use.

EVIDENCE-BASED NURSING CARE OF PERSONS WITH SCHIZOPHRENIA

Recovery is a long-term journey requiring various nursing interventions at different times. During exacerbation of symptoms, many patients are hospitalized for safety and medication adjustment. During periods of relative stability, the nurse and patient collaborate in developing recovery-oriented strategies that include maintaining a healthy lifestyle, developing positive coping skills, and seeking meaningful relationships. Schizophrenia research is ongoing, and the results are leading to new treatment approaches. It is critical that nurses continually seek out evidence-based strategies through accessing the best possible sources of evidence and formulating clinical questions See [Nursing Care Plan 24.1](#)

NURSING CARE PLAN 24.1

The Person with Schizophrenia

Arnold is a 53-year-old male with a history of schizophrenia with multiple hospitalizations. He was admitted per mental health court order to the inpatient mental health unit accompanied by the county sheriff. Arnold was given antipsychotic and antianxiety medication in the emergency room for the safety of himself and others after he attempted to strike an emergency room nurse. Arnold had become agitated and threatening while being removed from his family's farm, where he lived with his elderly mother for the past 30 years. Arnold refused to acknowledge that his parents had died.

Setting: Psychiatric Intensive Care Unit

Baseline Assessment: Arnold is dressed in a suit and dress shirt. On admission, he was also wearing a tie, which is his habit whenever he leaves his home. His tie, shoes, and belt were removed after arriving on the unit from the emergency room for safety reasons. Arnold wears his hair short, and he has been completing ADL. Arnold is watchful with a worried and anxious expression. He has a small stack of slightly used paper napkins stored between his shirt and suit jacket and holds a small stack of flattened single-serving milk cartons in his hand. Arnold does not believe that he has schizophrenia and that his previous hospitalizations were attempts by multinational corporations to keep him from following his false beliefs regarding his parent's wishes. Arnold is 5 ft 11 in., weighs 180 lb, BMI 25, BP 140/80, P 78, R 16. Denies suicidal thoughts. Denies using alcohol or illegal drugs. Even though he attended both parents' funerals, he continues to say they are merely away for a while. He has been taking his prescribed medications sporadically. Laboratory values are normal.

Associated Psychiatric Diagnosis
Schizophrenia, multiple episode, currently in acute episode

Medications
Risperidone (Risperdal), 2 mg BID
Lorazepam (Ativan), 2 mg PO for agitation PRN

Priority of Care: Alterations in Thought Process

Important Characteristics

- Delusional thinking (believes there is conspiracy against family by multinational corporations, and parents not really deceased)
- Auditory hallucinations (parents talking to him)
- Suspiciousness (refuses to use telephone or other technology)

Associated Considerations

- Uncompensated alterations in brain activity

Outcomes

Initial

- Decreased delusional thinking through accurate interpretation of environment
- Expresses less suspiciousness about family
- Decreased frequency of hearing voices
- Able to participate in activities of increasing length and complexity (e.g., sitting through group and group activities, able to make projects that require increased concentration and contain more steps)

Long-Term

- Able to identify, monitor, and recognize delusional thinking and hallucinations
- Able to use coping mechanisms that will help to minimize or control symptoms of delusions and hallucinations
- Able to develop a reasonable medication routine
- Reestablish self-care activities

Interventions

Interventions

Rationale

Ongoing Assessment

- Initiate a nurse–patient relationship by using an accepting, nonjudgmental approach.
- Be patient.
- Administer risperidone as prescribed. Observe for affect, side effects, and adverse effects. Begin teaching about the medication and its importance after symptoms subside.
- During hallucinations and delusional thinking, assess significance (what feelings is Arnold experiencing; what actions do the voices or his thoughts suggest he accomplish?). Reassure Arnold that you will keep him safe and that you are aware that his experiences are very real to him even though you may not be having the same experiences (Do not try to convince Arnold that his delusions are not true.) Redirect Arnold to here-and-now activities and experiences.
- Assess ability for self-care activities.
- A therapeutic relationship will provide support as Arnold begins to deal with his life change.
- Be patient because his brain is not processing information normally.
- Risperidone is a D2 and 5-HT2A antagonist and is indicated for the treatment of schizophrenia.
- It is important to understand the experience and context of the hallucinations and delusions to be able to provide appropriate interventions and redirect the patient to more reality-based activities. By avoiding arguments about the content of the patient’s delusional beliefs or the experiences of patient’s hallucinations, the nurse will enhance communication. Arguing about delusional thoughts or hallucinatory experiences just places the patient in a position to defend his beliefs.
- Disturbed thinking may interfere with Arnold’s ability to carry out ADLs.
- Determine the extent to which Arnold is willing to trust and engage in a relationship.
- Determine the length of time Arnold can attend to conversation or activity with others.
- Make sure Arnold swallows pills. Monitor for relief of positive symptoms using a standardized measure such as the SAPS. Assess side effects, especially extrapyramidal. Monitor blood pressure for orthostatic hypotension and body temperature increase (NMS).
- Assess the meaning of the hallucinations or delusions of the patient. Monitor whether he is a danger to himself or others. Determine whether patient can be directed to a more reality-based activity.
- Continue to assess: Determine whether Arnold can manage his own self-care.

Priority of Care: Lack of Recognition of Illness and Consequences

Important Characteristics

- Displaces fear of impact of losing parents and home
- Does not perceive personal relevance to behavior
- Unable to admit impact of schizophrenia on life pattern

Associated Considerations

- Anxiety about leaving home
- Lack of control of life situation
- Threat of unpleasant reality

Outcomes

Initial

- Avoid hurting self or assaulting other patients or staff.
- Decreased anxiety.

Long term

- Recognize that parents have died.
- Develop coping skills to address moving to a new house.

Interventions

Interventions	Rationale	Ongoing Assessment
<ul style="list-style-type: none"> • Acknowledge patient's anxiety about parents' absence and loss of family home. • Be genuine and empathic. • Prioritize goals by including maintaining safety, learning about prescribed medication, and participation in treatment activities. • Use medications to help the patient relax and maintain more calm: administer lorazepam, 2 mg, for agitation. The PO route is preferable to injection, so offer the patient this choice long before he has lost control. 	<ul style="list-style-type: none"> • Beginning with the facts that Arnold accepts as true helps establish a supportive, communication alliance. • Arnold will benefit from your ability to understand his experience and express that understanding while presenting reality. • By having choices, he will begin to develop a sense of control over his behavior. • Exact mechanisms of action are not understood, but medication is believed to potentiate the inhibitory neurotransmitter GABA, relieving anxiety and producing sedation. 	<ul style="list-style-type: none"> • Assess the patient's ability to hear you and respond appropriately to your comments and requests; assess the patient's ability to concentrate on what is being said and happening around him. • Assess for evidence that the client is less frightened with less potential for striking out. • Observe the patient's nonverbal communication for evidence of increased agitation. • Observe for a decrease in agitated behavior. • Offering this to the patient early, as fear and agitation are beginning to become evident, prevents the potential for the patient to lose control.
Evaluation		
Outcomes	Revised Outcomes	Interventions
<ul style="list-style-type: none"> • Arnold gradually decreased agitated behavior. • Lorazepam was given regularly for first 2 days. <p>ADL, activity of daily living; BID, twice a day; GABA, gamma-aminobutyric acid; NMS, neuroleptic malignant syndrome; PO, oral; SAPS, Scale for the Assessment of Positive Symptoms.</p>	<ul style="list-style-type: none"> • Demonstrate control of behavior when discussing realistic discharge plans. 	<ul style="list-style-type: none"> • Problem-solve possible scenarios for discharge.

Mental Health Nursing Assessment

The nursing assessment should include the biologic, psychological, and social aspects because schizophrenia affects all aspects of the person's life. Not only are symptoms assessed, but strengths are also important in the assessment process.

Physical Health

The nurse should first determine whether any underlying medical disorders are present, particularly those associated with schizophrenia, such as DM,

hypertension, and cardiac disease, or a family history of such disorders. Usually, a medical examination is conducted by primary care providers prior to initiation of mental health care. People with schizophrenia have a higher mortality rate from physical illness and often have smoking-related illnesses, such as emphysema as well as other pulmonary and cardiac problems (Seeman, 2019).

Physical Functioning

Physical abilities can be a strength; the potential to maintain optimal physical health should be assessed. Self-care often deteriorates in schizophrenia; sleep may be nonexistent during acute phases. Information regarding physical functioning may best be collected from family members.

Nutrition

A nutritional history should be completed to determine baseline eating habits and preferences. Taking baseline measures for metabolic syndrome is highly recommended and should include weight, waist circumference, cholesterol, and blood sugar (Hammoudeh et al., 2020). A healthy diet is important in managing the illness. Medications can alter normal nutrition, leading to excessive consumption of calories.

Medication

The nurse should obtain a complete list of medications that the patient is taking, including over-the-counter (OTC) agents and herbal supplements. Before initiation of psychiatric medications, standardized assessment of abnormal motor movements should be conducted using one of several assessment tools designed for that purpose, such as the Abnormal Involuntary Movement Scale (AIMS) (see Appendix B), the Dyskinesia Identification System (DISCUS) (Sprague & Kalachnik, 1991), or the Simpson-Angus Rating Scale (Simpson & Angus, 1970), which is designed for Parkinson symptoms.

Substance Use (Alcohol, Illicit Drugs, Tobacco)

The nurse should ask specific questions about alcohol, drug, and tobacco use. The use of these substances is quite common with people with schizophrenia and will significantly influence the treatment approach.

Psychosocial Assessment

The individual who is in an acute phase may be unable to provide an accurate history of early psychosocial issues. Family members' reports help in detailing occurrences of psychotic symptoms of delusions and hallucinations; however, onset of negative symptoms may be more difficult to date. In fact, negative symptoms vary from a slight deviation from normal to a clear impairment. Negative symptoms probably occur earlier than positive symptoms but are less easily recognized. Several assessment scales have been developed to help evaluate clusters of positive and negative symptoms (see [Box 24.4](#)).

Mental Status and Appearance

The patient may look eccentric or disheveled or have poor hygiene and bizarre dress. The patient's posture may suggest lethargy or stupor.

BOX 24.4

Rating Scales for Use with Schizophrenia

SCALE FOR THE ASSESSMENT OF NEGATIVE SYMPTOMS (SANS)

Available from Nancy C. Andreasen, MD, PhD, Department of Psychiatry, College of Medicine, The University of Iowa, Iowa City, IA 52242. Copyright 1984.

SCALE FOR THE ASSESSMENT OF POSITIVE SYMPTOMS (SAPS)

ABNORMAL INVOLUNTARY MOVEMENT SCALE (AIMS)

Guy, W. (1976). *ECDEU: Assessment manual for psychopharmacology* (DHEW Publication No. 76-338). Department of Health, Education, and Welfare, Psychopharmacology Branch.

BRIEF PSYCHIATRIC RATING SCALE (BPRS)

Overall, J. E., & Gorham, D. R. (1988). The Brief Psychiatric Rating Scale (BPRS): Recent developments in ascertainment and scaling. *Psychopharmacology Bulletin*, 24, 97-99.

DYSKINESIA IDENTIFICATION SYSTEM: CONDENSED USER SCALE (DISCUS)

Sprague, R. L., & Kalachnik, J. E. (1991). Reliability, validity, and a total score cutoff for the Dyskinesia Identification Scale System: Condensed User Scale (DISCUS) with mentally ill and mentally retarded populations. *Psychopharmacology Bulletin*, 27(1), 51-58.

SIMPSON-ANGUS RATING SCALE

Simpson, G. M., & Angus, J. W. S. L. (1970). A rating scale for extrapyramidal side effects. *Acta Psychiatrica Scandinavica*, 212(suppl), 11-19. Copyright 1970 Munksgaard International Publishers, Ltd.

Mood and Affect

Patients with schizophrenia often display altered mood states. In some cases, they may show heightened emotional activity; others may display severely limited emotional responses. Affect, the outward expression of mood, is categorized on a continuum: flat (i.e., emotional expression entirely absent), blunted (i.e., expression of emotions present but greatly diminished), and full range of expression. Inappropriate affect is marked by incongruence between the emotional expression and the thoughts expressed (e.g., laughing when telling a sad story). Other common emotional symptoms include the following:

- **Affective lability**—abrupt, dramatic, unprovoked changes in type of emotions expressed
- **Ambivalence**—the presence and expression of two opposing feelings, leading to inaction
- **Apathy**—little emotional expression, diminished interest and desire

Speech

Thought content and other mental processes are expressed in speech. Both content and speech patterns should be assessed by the nurse. Speech content may include obvious obsessions or delusions, loose associations, or flight of ideas. In some instances, as already noted, patients make up their own words (neologisms). Speech may be pressured (words seem to rapidly jump out without

pauses) or slow. The nurse should note any difficulty in articulating words (dysarthria) or difficulty in swallowing (dysphagia) as indicators of medication-related side effects.

Thought Process Assessment

Thought process assessment includes determining if any hallucinations, delusions, disorganized communication, or cognitive impairments are present. Because thought process assessment is critical in the nursing assessment, each area is discussed separately in the following sections.

Hallucinations

Hallucinations are the most common example of disturbed sensory perception observed in patients with schizophrenia. Hallucinations are experienced in the sensory modalities (visual, auditory, gustatory, tactile, olfactory); however, auditory hallucinations are the most common type in schizophrenia. Some specific hallucinations may be sufficient to diagnose schizophrenia, such as hearing voices, conversing with each other, or carrying on a discussion with someone who is not there. Because most individuals will not spontaneously share their hallucinatory experiences with an interviewer, the nurse may need to rely on indirect evidence in the patient's behavior, such as (1) pauses during conversations in which the individual seems preoccupied or appears to be listening to someone other than the interviewer, (2) looking toward the perceived source of a voice, or (3) responding to the voices in some manner. Although patients may not spontaneously share their hallucinations, many validate observations of the examiner or admit to a history of hallucinations when asked (see [Box 24.5](#)). If a patient has command hallucinations, it is important for the safety of the person and others to know what the voices are telling the patient to do.

Delusions

Delusions are different from strongly held beliefs. Delusions do not change even

though strong evidence contradicts the belief. The person continues to hold the belief despite contradictory evidence (APA, 2013). The person's culture must be considered when evaluating delusions. Delusional beliefs are those not sanctioned or held by a cultural or religious subgroup.

Bizarre delusions alone are sufficient to diagnose schizophrenia (APA, 2013). Bizarre delusions are those beliefs that are impossible, illogical, and not derived from ordinary life experiences. Bizarre delusions often include delusions of control (that some outside force controls thoughts and actions), thought broadcasting (that others can read or hear one's thoughts), thought insertion (that someone has placed thoughts into one's mind), and thought withdrawal (that someone is removing thoughts from one's mind). For example, a patient who has been seeing a hypnotist for 2 months reports that the hypnotist continued to read his mind and was "picking his brain away piece by piece." Another patient was convinced that a computer chip was placed in her vagina during a gynecologic examination and that this somehow directly influenced her physical movements and her thoughts.

Remember Arnold?

He believes that his parents are still alive and that they will return. He refuses to leave the farm and insists that everything is left as it is.

Nonbizarre delusions generally have themes of jealousy and persecution and are derived from plausible life experiences. For example, a woman believes that her husband, from whom she has recently separated, is trying to poison her, or a man who believes that members of the Mafia are trying to kill him because, when he was in high school, he reported to the principal that several of his classmates were selling drugs at school (APA, 2013).

Assessing and judging the content of the delusion and exploring other aspects of the delusional experience are helpful in understanding the significance of these false beliefs. The underlying feeling that accompanies the delusion (i.e., fear or inflated self-esteem) should be explored. Other aspects to consider include the conviction with which the delusion is held; the extent to which other aspects of the individual's life are incorporated or affected by the delusion; the degree of internal consistency, organization, and logic evidenced in the delusion; and evaluating the amount of pressure (in terms of preoccupation and concern)

individuals feel in their lives as a result of the delusion ([Box 24.6](#)).

BOX 24.5 • THERAPEUTIC DIALOGUE: THE PATIENT WITH HALLUCINATIONS

The following conversation took place in Arnold's room during the night checks. The nurse observed that Arnold was talking with someone, but no one else was in the room.

INEFFECTIVE APPROACH

Nurse: Arnold?

Arnold: Yeah?

Nurse: Whom are you talking to?

Arnold: My mother visits me at night. I am telling her about my day.

Nurse: You know, Arnold, you are having a hallucination. Your mother died a few weeks ago.

Arnold: She did not. She is away for a while, but she will be back soon.

Nurse: Arnold. (Looks at nurse.) You are going to have to accept that your mother is gone.

Arnold: Oh yeah? What do you know?

Nurse: Well, we can talk about it in the morning.

Arnold: You don't know what you are talking about.

EFFECTIVE APPROACH

Nurse: Arnold?

Arnold: Yeah?

Nurse: Are you talking to someone?

Arnold: Yes, she visits me at night?

Nurse: Oh, does she talk to you?

Arnold: Yes, she asks me about my day. She visits in the evening.

Nurse: Is there anything else you talk about?

Arnold: No, she leaves after I tell her.

Nurse: OK, how do you feel when she visits you?

Arnold: A little sad, but I like to tell her about my day.

Nurse: A little sad?

Arnold: Yeah, I wish I could see her more.

Nurse: Sounds like you are lonely?

Arnold: Yea, it's nice when you talk with me.

Nurse: I can do that. If you are not asleep when I finish rounds, we can talk more.

CRITICAL THINKING CHALLENGE

- How did the nurse's impatience translate into Arnold's response in the first scenario?
- What effective communicating techniques did the nurse use in the second scenario?

Disorganized Communication

Abrupt shifts in the focus of conversation, which are often altered in schizophrenia, are typically symptomatic of disorganized thinking. Impaired verbal fluency (i.e., ability to produce spontaneous speech) is commonly present. The most severe shifts in focus may occur after only one or two words (i.e., word salad), after one or two phrases or sentences (i.e., flight of ideas or loose associations), or somewhat less severely as a shift that occurs when a new topic is repeatedly suggested and pursued from the current topic (i.e., tangentiality).

Cognitive Impairments

Mental status assessment focuses on eliciting indications of cognitive impairments associated with schizophrenia. Although these impairments vary widely from patient to patient, several primary problems have been identified:

- Attention may be increased and sustained on external stimuli over a period of time (hypervigilance).
- The ability to distinguish and focus on relevant stimuli may be diminished.
- Familiar cues may go unrecognized or be improperly interpreted.
- Information processing may be diminished, leading to inappropriate or illogical conclusions from available observations and information (Dondé et al., 2018; John et al., 2018).

BOX 24.6 • THERAPEUTIC DIALOGUE: THE PATIENT WITH DELUSIONS

John joined the nurse in a game of pool. The following conversation occurred as they played.

INEFFECTIVE APPROACH

John: The CIA put a transmitter in my molar, here (points to his right cheek).

Nurse: No one would put a transmitter in your tooth; come on, the CIA isn't looking for you.

John: Yeah, they want to monitor me while I'm here. I know that they have the real Osama bin Laden here in the hospital. They are trying to get the President to intervene with the Michigan Militia. Mark from Michigan told me that.

Nurse: Osama bin Laden can't possibly be here; he died years ago.

John: Maybe—but that was an imposter. They're just trying to keep people from knowing what they're doing.

Nurse: John, Osama bin Laden isn't in the hospital; if he were, I would know it because I work here.

John: (With anger) You don't know anything! You are probably working for the CIA too. I have nothing else to say to you.

EFFECTIVE APPROACH

John: The CIA put a transmitter in my molar, here (points to his right cheek).

Nurse: Oh. Which balls are mine?

John: You get the striped ones. Yeah, they want to monitor me while I'm here. I know that they have the real Osama bin Laden here in the hospital. They are trying to get the President to intervene with the Michigan Militia. Mark from Michigan told me that.

Nurse: Well, I don't know anything about that, but I want you to know that we will keep you safe.

John: Maybe...

Nurse: You sound a little overwhelmed with all the information you have.

John: No, no. I can handle it. The CIA can't do anything to me. I'll never talk.

Nurse: I thought they could hear you when you talk to me.

John: Huh? Oh, that transmitter is so that they can send me misinformation. They send a tower of babble to my brain. They are trying to confuse me so that I stay away from Osama Bin Laden. They all think they can keep me from my mission.

Nurse: Who are they?

John: Everyone in the government. The CIA, FBI, ATF, IRS—all those alphabets.

Nurse: So, everyone in the government is trying to get to you?

John: Well, maybe not everybody. Just the ones that care about money and the militia. I don't think they care about me much in Commerce or Health and Human Services. Although they'd care too if they knew.

Nurse: I would think that's pretty frightening to have all these people out looking for you. You must be scared a lot.

John: It's scary, but I can handle it. I've handled it all my life.

Nurse: You've been in scary situations all your life?

John: Yeah. I don't know. Maybe not scary, just hard. I never seemed to be able to do as well as my parents wanted—or as I wanted.

CRITICAL THINKING CHALLENGE

- How did the nurse's argumentative responses cause the patient to react in the first scenario?
- What effective communication techniques did the nurse use in the second scenario?

Cognitive impairments are not easy to recognize. By relying only on clinical assessment, the nurse can miss the extent of the impairment. Using a standardized instrument can provide a screening measurement of cognitive function (see [Chapter 11](#)). If impairment exists, neuropsychological testing by a qualified psychologist may be necessary.

Memory and Orientation

Impairment in orientation, memory, and abstract thinking is often present. Orientation to time, place, and person may remain relatively intact unless the patient is particularly preoccupied with delusions and hallucinations. Although all aspects of memory may be affected in schizophrenia, registration or the ability to recall within seconds of newly learned information may be particularly diminished. This affects the individual's short- and long-term memory. The ability to engage in abstract thinking may be impaired (see [Box 24.7](#)).

Insight and Judgment

Insight and judgment are closely related to each other. Individuals display insight when they recognize that their hallucinations or delusions are symptoms of a

mental disorder. Judgment is the ability to decide or act about a situation. If judgment is poor, the person may not recognize personal vulnerabilities and consequently engages in detrimental behavior. For example, the individual may be taken advantage of by others or fail to realize a potentially dangerous situation.

Behavioral Responses

During periods of psychosis, unusual or bizarre behavior often occurs. These behaviors can usually be understood within the context of the patient's disturbed thinking. The nurse needs to understand the significance of the behavior to the individual. For example, one patient moved the family furniture into the yard because he thought that evil spirits were hiding in the furniture. His bizarre behavior was an attempt to protect his family. Another patient painted a sequence of numbers on his bedroom walls. He said that the numbers were the language of the angels. His delusional thoughts were the basis of his behavior.

Because of the negative symptoms, specifically avolition, patients may not seem interested or organized enough to complete normal daily activities. They may stay in bed most of the day or refuse to take a shower. Many times, they agree to get up in the morning and go to work, but they never get around to it. Several specific behaviors are associated with schizophrenia, including stereotypy (i.e., idiosyncratic, repetitive, purposeless movements); echopraxia (i.e., involuntary imitation of others' movements); and waxy flexibility (i.e., posture held in odd or unusual fixed positions for extended periods). In some cases, certain behaviors need to be evaluated carefully to distinguish them from movements that are associated with medication-related side effects, such as grimacing, stereotypical behavior, or agitation.

BOX 24.7

Arnold's Cognitive Symptoms

Arnold's symptoms of schizophrenia began long before he was actually diagnosed. Throughout school, he had difficulty learning new material. His teachers would describe him as being "slow" or "inattentive." Because he appeared to be functioning normally, his teachers and family attributed his poor academic behavior to lack of interest. His father would often get frustrated with him because he would spend many

hours in his bedroom and would not help out on the farm. When prodded to complete schoolwork or a household task, he would often get distracted before finishing the tasks. Family members and teachers quickly learned to provide several prompts for Arnold to complete a task. As he progressed to high school, he was labeled as a “slow learner” and assigned to less demanding classes.

The reality was that Arnold was experiencing unrecognized prodromal cognitive symptoms of schizophrenia. He was having difficulty remembering his assignments. He was having difficulty grasping concepts that other students seemed to easily understand. He was becoming frustrated with his difficulty and retreated to his room. He waited for specific directions that he could easily process. His thinking was concrete, and he had difficulty expressing himself. When he was bombarded with several directions at once, he could not process any of the directions. In his frustration, he would throw objects, frightening others. His family was very concerned with the changes that were occurring with their once easy-going son.

Self-Concept

In schizophrenia, self-concept is usually poor. Patients often are aware that they are hearing voices that others do not hear. They recognize that they are different from others and are often scared of “going crazy.” Many are aware of the loss of expectations for their future achievements. The pervasive stigma associated with having a mental illness contributes to the poor self-concept. Body image can be disturbed, especially during periods of hallucinations or delusions. For example, one patient believed that her body was infected with germs, and she could feel them eating away her insides.

Stress and Coping Patterns

Stressful events are often linked to psychiatric symptoms. It is important to determine stresses from the patient’s perspective because a stressful event for one may not be stressful for another. It is also important to determine typical coping patterns, especially negative coping strategies, such as the use of substances or showing aggressive behavior.

Consider This:

Recall Arnold’s symptoms? They appeared after the stress of his parents’ death.

Social Network

Several difficulties involving social functioning occur in schizophrenia. As the disorder progresses, individuals can become increasingly socially isolated. On a one-to-one basis, this occurs as the individual seems unable to connect with people in their environment. Several aspects of symptoms already discussed can contribute to this. For example, emotional blunting and anhedonia (the inability to experience pleasure) result in an experience of not being engaged in activities and relationships.

Interpretation of facial expressions and affect displayed by others is often problematic for people with schizophrenia. Cognitive deficits affect social relationships when individuals are unable to recall past interactions and have problems with decision-making and judgment. Other behaviors that affect social relationships are poverty of speech and language and the inability to complete ADLs, which results in poor hygiene, malnutrition, and social isolation.

Functional Status

Functional status of patients with schizophrenia should be assessed initially and at regular intervals. Level of independence, ability to work, ability to maintain an independent living environment, and self-care should be evaluated.

Support Systems

In schizophrenia, support systems become very important in maintaining the patient in the community. The individual may become socially isolated if the treatment and management occur in long-term care facilities and group homes, away from family and friends. One challenge is to identify and maintain the patient's links with family and significant others. Assessment of the formal support (e.g., family, health care providers) and informal support (e.g., neighbors, friends) should be conducted.

Quality of Life

People with schizophrenia often have a poor quality of life, especially older people, who may have spent many years in long-term hospitals. The nurse should assess the patient's quality of life and how it could be improved. Simple changes, such as arranging for a different roommate or improving access to social activities by meeting transportation needs, can greatly improve a patient's quality of life.

Strength Assessment

An important part of recovery is identification of personal and family strengths. Because schizophrenia is usually diagnosed at a young age, the person may be physically fit with little evidence of chronic illness. As the assessment is completed, strengths will emerge. Family support is critical for a person with schizophrenia. Intellectual ability and coping with stress are areas that can be strengths. The following questions are examples that can be used in assessing strengths.

- What do you do for relaxation, fun?
- How do you manage stressful events?
- How do you cope with the voices, thoughts, or impulses?
- Who do you talk with when you are upset?
- Are you hopeful about the future, and if so, what gives you hope for the future?

CLINICAL JUDGMENT

People with schizophrenia have a variety of nursing care needs because of the complexity of this chronic and difficult-to-treat illness. These needs emerge at different times and in different manifestations of the illness. Nurses need to consider the point in time during the progression of schizophrenia, the acceptability of its treatment to the individual, and the availability of community resources in order to best plan care. In many ways, treatment needs should be

considered through a matrix of factors including (1) the stage of the illness (prodromal, acute, stable, and recovering); (2) the type, mixture, and intensity of symptoms; (3) the medication effects and side effects; (4) the method and availability of treatment; and (5) sources of social support and recovery-based care. For example, during an episode of psychosis, a nurse needs to be aware of the **symptoms** that affect the patient's **safety**. **Hallucinatory voices** may be telling the individual to self-injure or injure others. **Delusional thinking** may result in **suspicion** or **isolation**. **General functioning and basic care** may be compromised: **sleep** patterns may be severely disrupted, the person may be **undernourished** due to inability to obtain food or fear of eating. There may be **hygiene** issues that interfere with the person's ability to engage in social activities. An acute psychotic episode early in the disease may be accompanied by **grief and loss** due to changes in the expectations of the individual and their family. **Mood disturbances**, specifically depression, may be a priority later in the course of the disorder and may require a significant plan to avoid suicide. **Motivation** may be an issue during the course of the illness: early on as the individual and family wrestle with the implications of the illness and later as the chronicity of the symptoms continues. **Medication management** requires different assessments over the course of the illness. Early on, patients need considerable encouragement to continue taking medications that do not always make them feel comfortable and are not always believed to be necessary. In order to help patients take medications to control symptoms, dosage regimens need to be convenient and easy to follow; medications need to be sufficient to control symptoms without burdening the patient with unpleasant side effects. Long-acting injectable antipsychotic medications may be an answer to the issues of convenience and help to avoid relapse. Late in the illness, medication management needs to be **a mutual process**, particularly for patients who have managed their illness well. **Community resources** differ based on funding and location: rural versus urban; state priorities versus county and city policies. For many individuals with schizophrenia, the course of their illness is not just dependent on their symptoms but also on the availability of resources to help them manage their illness. A very careful and ongoing assessment of needs and issues is important throughout recovery.

NCLEXNOTE When assessing a patient with schizophrenia, the nurse should prioritize the severity of the current responses to the disorder. If hallucinations are impairing function, then managing hallucinations is a priority, and medications are needed immediately. If hallucinations are not a problem,

however, coping with negative symptoms becomes a priority.

THERAPEUTIC RELATIONSHIP

Development of the therapeutic nurse-patient relationship centers on developing trust, accepting the person as a worthy human being, and infusing the relationship with hope. People with schizophrenia are often reluctant to engage in any relationship because of previous rejection and, in some instances, an underlying suspiciousness, which is a part of the illness. They are often trying to trust their own thoughts and perceptions, so interactions with another human being may prove to be too overwhelming. If they are hallucinating, their images of other people may be distorted and frightening as well.

The nurse should approach the patient in a calm and caring manner. Engaging the patient in a relationship may take time, but it begins with the first encounter. Short time-limited interactions are best for a patient who is experiencing psychosis. Being consistent in interactions and following through on promises will help establish trust within the relationship.

Establishing a therapeutic relationship is crucial, especially with patients who deny that they are ill. Patients are more likely to agree to and continue treatment if these recommendations are made within the context of a safe, trusting relationship. Even if some patients deny having mental illness, they may take medication and attend treatment activities because they trust the nurse (Jaeger et al., 2014).

Furthermore, for long-term care and outcomes, recovery-oriented relationships are important. Using the recovery model, all efforts should be made to individualize treatment. Care should be person-centered through partnering with the patient in all aspects of care and encouraging self-direction. Treatment should be focused on strengths and the empowerment of the individual. Patients need encouragement to see that although their diagnosis may seem devastating, recovery is possible (Lean et al., 2019).

MENTAL HEALTH NURSING INTERVENTIONS

Establishing Recovery and Wellness goals

Nurses should aim to help their patients with schizophrenia to maximize their health, given this chronic illness. Goals need to take into consideration the symptoms that accompany schizophrenia, as well as the side effects of the medications used to treat schizophrenia. Helping people to recover and feel the best they can physically with this chronic illness includes the development of healthy day-to-day habits around hygiene, exercise, and nutrition. Nurses also need to be aware of specific issues that can arise for people who have schizophrenia around temperature regulation and fluid and electrolyte balance.

Physical Care

For many people with schizophrenia, the plan of care will include specific interventions to enhance self-care, nutrition, and overall health knowledge. Negative symptoms commonly leave patients unable to initiate these seemingly simple activities. Developing a daily schedule of routine activities (e.g., showering, shaving) can help the patient structure the day. Most patients actually know how to perform self-care activities (e.g., hygiene, grooming) but lack motivation (avolition) to carry them out consistently. Interventions include developing a schedule with the patient for various hygiene-related activities and emphasizing the importance of maintaining appropriate self-care activities. Given the problems related to attention and memory in people with schizophrenia, education about these areas requires careful planning.

Activity, Exercise, and Nutritional Interventions

Encouraging activity and exercise is necessary, not only to maintain a healthy lifestyle but also to counteract the side effects of psychiatric medications that cause weight gain. Because the diagnosis is usually made in late adolescence or early adulthood, it is possible to establish solid exercise patterns early.

During episodes of acute psychosis, patients are sometimes unable to focus on eating. Often when patients begin antipsychotic medication, normal satiety and hunger responses change, and overeating or weight gain can become a problem. Patients report that their appetites increase and cravings for food develop when some medications are initiated. Promoting and maintaining healthy nutrition is a key intervention. Monitoring calorie intake is also important because of the

effect many medications have on eating habits.

Weight gain is one of the reasons some patients stop taking their medications. Increased weight places patients at greater risk for several health problems, such as type II DM and early death. Monitoring for DM and managing weight are important activities for all health care providers. Patients should be screened for risk factors of DM, such as family history, obesity as indicated by a body mass index (BMI) exceeding or equal to 27, and age older than 45 years. Patients' weight should be measured at regular intervals and the BMI calculated. Blood pressure readings should be taken regularly. Laboratory findings for triglycerides, high-density lipoprotein cholesterol, and glucose level should be monitored and reviewed regularly. All health care providers should be alert to the development of hyperglycemia, particularly in patients known to have DM who begin taking second-generation antipsychotic agents. A program to address weight gain should be initiated at the earliest sign of weight gain (probably between 5 and 10 pounds over desired body weight). Reduced caloric intake may be accomplished by increasing the patient's access to affordable, healthful, and easy-to-prepare foods. Behavioral management of weight gain includes keeping a food diary, diet teaching, and support groups. Setting small goals and offering a lot of encouragement can lead to some success. (Daumit et al., 2020).

Thermoregulation Interventions

Patients with schizophrenia may have disturbed body temperature regulation. In winter, they may seem to be oblivious to cold weather. In the heat of summer, they may dress for winter. Observing patients' responses to environmental temperatures helps in identifying problems in this area. In patients who are taking psychiatric medications, body temperature needs to be monitored, and the patient needs to be protected from extremes in temperature.

Fluid Balance

Some persons with schizophrenia develop disturbed fluid and electrolyte balance. Nurses should observe for polydipsia (frequently drinking an excessive amount of fluids) or frequent incontinence. These individuals are obsessed with

drinking water and compulsively consume fluids. For persons with schizophrenia who demonstrate polydipsia, regulation of their fluid intake is disturbed, resulting in an abnormally low serum sodium level, which can lead to severe water intoxication, a medical emergency.

Nursing interventions include teaching and assisting the patient to develop self-monitoring skills. Fluid intake and weight gain should be monitored to control fluid intake and reduce the likelihood of developing water intoxication. Patients with mild polydipsia are easily treated in outpatient settings and benefit from educational programs that teach them to monitor their own urine's specific gravity and daily weight gains. Patients with moderate polydipsia may respond well to education but still have a more difficult time controlling their own fluid intake, which requires more careful monitoring of intake and weight throughout the day. Patients with severe polydipsia require considerable assistance, probably in an inpatient unit, to restrict their continual water-seeking behavior. These patients may create disruption on the unit, so they are best managed by one-on-one observation to redirect their behavior.

Wellness Challenges

The challenges to the overall wellness of people with schizophrenia include the symptoms of schizophrenia, the effects of medication treatment, and the circumstances around where they live, and their social connections. One example could be addressing a goal related to a healthy diet and exercise. Symptoms of schizophrenia that must be considered are ambivalence, avolition, and lack of motivation. Effects and side effects of medication treatment may include weight gain and sleepiness. Living and social circumstances may include living in group homes with limited access to consistently healthy food, limited funds to purchase healthy food, or living in food deserts in cities or at great distances from food markets in rural towns and communities. These living and social circumstances may limit exercise interventions because housing locations may not be in the safest areas of a city or town.

Wellness goals need to be manageable and specific. Creating goals that focus on small steps is less overwhelming. For instance, selecting a goal to lose 25 pounds may be overwhelming. More manageable goals could be to eat French fries only twice a week and to walk 10 minutes twice a day around the yard of the adult foster care home. Supporting these goals would include conversations

around the accomplishment of these activities, as well as measuring outcomes like weight, blood pressure, and hemoglobin A1c, if indicated. Goals can be revised based on levels of success.

Medication Interventions: Antipsychotics

Antipsychotic medications are the treatment of choice for patients with psychosis. Antipsychotic drugs are used because they have the general effect of blocking dopamine transmission, leading to a decrease in psychotic symptoms (see [Chapter 12](#)). Some medications also block other receptors of other neurotransmitters to varying degrees (see [Table 24.1](#)).

The prescription of first-generation antipsychotics (e.g., haloperidol, chlorpromazine) decreased dramatically with the introduction of second-generation antipsychotics. However, it is important that medication choice be individualized based on each patient's experience and preference, as well as the side effect profiles of selected drugs rather than to limit drug selection to one type or class of antipsychotic medication. This is particularly true during the acute phase of the illness for people with schizophrenia who are known to respond to treatment.

TABLE 24-1: SELECTED ANTIPSYCHOTIC DRUGS

Generic Name	Trade Name	Dosage Range for Adults (mg/d)
Second-Generation Antipsychotics		
Aripiprazole	Abilify	10–15
Asenapine	Saphris	10–20
Cariprazine	Vraylar	1.5–6
Clozapine	Clozaril	200–600
Lumateperone	Caplyta	42
Risperidone	Risperdal	4–16
Olanzapine	Zyprexa	10–20
Paliperidone	Invega	3–12
Quetiapine	Seroquel	300–400
Ziprasidone	Geodon	40–160
Lurasidone	Latuda	40–80

Selected First-Generation Antipsychotic Drugs Used to Treat Psychosis in the United States

Chlorpromazine	NA*	30–800
Fluphenazine	NA	0.5–20
Haloperidol	Haldol	1–15
Loxapine	Loxitane	20–250
Perphenazine	NA	4–32
Pimozide	NA	1–10
Thiothixene	Navane	5–25
Trifluoperazine	NA	5–25

*Not Applicable. No longer available as proprietary formulations.

Second-generation antipsychotic drugs including risperidone (Risperdal), olanzapine (Zyprexa), quetiapine (Seroquel), paliperidone (Invega), ziprasidone (Geodon), aripiprazole (Abilify), iloperidone (Fanapt), asenapine (Saphris), lurasidone (Latuda), cariprazine (Vraylar), and lumateperone (Caplyta) are available in a variety of formulations. See [Box 24.8](#) for more information about risperidone. They are effective in treating both negative and positive symptoms. These drugs also target other neurotransmitter systems, such as serotonin and glutamate. This is believed to contribute to their antipsychotic effectiveness.

Administering Medications

Nursing interventions during the initial acute phase of schizophrenia include prompt, safe, and informed administration of antipsychotic medications. Generally, it takes about 1 to 2 weeks for antipsychotic drugs to effect a change in symptoms. During the stabilization period, the selected drug should be given an adequate trial, generally 6 to 12 weeks, before considering a change in the drug prescription. For maximum absorption, ziprasidone and lurasidone should be given with food. Ziprasidone should be taken with a high-fat meal of 500 calories. For lurasidone, 350 calories should be eaten when administering this (Pfizer, 2020). If treatment effects are not seen, a different antipsychotic agent may be tried. Clozapine is used when no other second-generation antipsychotic is effective; see [Box 24.9](#) for more information about clozapine.

Adherence to a prescribed medication regimen is the best approach to prevent relapse. Unfortunately, adherence to the second-generation antipsychotic agents

is not improved from the first-generation antipsychotic. The use of long-acting injectables has improved compliance outcomes (Kane et al., 2020). [Box 24.10](#) provides evidence related to interventions that promote medication adherence for patients with schizophrenia.

Patients with schizophrenia generally face a lifetime of taking antipsychotic medications. Rarely is discontinuation of medications prescribed; however, many patients stop taking medications on their own. Some conditions do require the cessation of medication use, such as **neuroleptic malignant syndrome** (see later discussion), **agranulocytosis** (i.e., dangerously low level of circulating neutrophils), or drug reaction with eosinophilia and systemic symptoms (DRESS) (i.e., fever with a rash and/or swollen lymph glands). Discontinuation is also an option when **tardive dyskinesia** develops. Discontinuation of medications, other than in the circumstances of a medical emergency, should be achieved by gradually lowering the dose over time. This diminishes the likelihood of withdrawal symptoms.

BOX 24.8

Drug Profile: Risperidone (Risperdal)

DRUG CLASS: Atypical antipsychotic

RECEPTOR AFFINITY: Antagonist with high affinity for dopamine D₂ and serotonin 5-HT₂, also histamine (H₁) and α_1 -, α_2 -adrenergic receptors, weak affinity for D₁ and other serotonin receptor subtypes; no affinity for acetylcholine or β -adrenergic receptors

INDICATIONS: Treatment of schizophrenia; short-term treatment of acute manic or mixed episodes associated with bipolar I disorder; and irritability associated with autistic disorder in children and adolescents, including symptoms of aggression toward others, deliberate self-injuriousness, temper tantrums, and quickly changing moods

ROUTES AND DOSAGE: 0.25-, 0.5-, 1-, 2-, 3-, and 4-mg tablets and liquid concentrate (1 mg/mL); orally disintegrating tablets, 0.5, 1, 2, 3, and 4 mg

Adult: Schizophrenia: Initial dose: typically, 1 mg BID. Maximal effect at 6 mg/day. Safety not established above 16 mg/day. Use lowest possible dose to alleviate symptoms.

Bipolar mania: 2 to 3 mg/day

Geriatric: Initial dose, 0.5 mg/day; increase slowly as tolerated

Children: 0.25 mg/day for patients <20 kg and 0.5 mg/day for patients >20 kg

HALF-LIFE (PEAK EFFECT): Mean, 20 h (1 h; peak active metabolite = 3 17 h)

SELECT SIDE EFFECTS: Insomnia, agitation, anxiety, extrapyramidal symptoms, headache, rhinitis, somnolence, dizziness, headache, constipation, nausea, dyspepsia, vomiting, abdominal

pain, hypersalivation, tachycardia, orthostatic hypotension, fever, chest pain, coughing, photosensitivity, weight gain

BOXED WARNING: Increased mortality in older patients with dementia-related psychosis

WARNING: Rare development of NMS. Observe frequently for early signs of tardive dyskinesia. Use caution with individuals who have cardiovascular disease; risperidone can cause electrocardiographic changes. Avoid use during pregnancy or while breast feeding. Hepatic or renal impairments increase plasma concentration.

SPECIFIC PATIENT/FAMILY EDUCATION

- Notify your prescriber if tremor, motor restlessness, abnormal movements, chest pain, or other unusual symptoms develop.
- Avoid alcohol and other CNS depressant drugs.
- Notify your prescriber if pregnancy is possible or if planning to become pregnant. Do not breastfeed while taking this medication.
- Notify your prescriber before taking any other prescription or OTC medication.
- May impair judgment, thinking, or motor skills; avoid driving or potentially other hazardous tasks.
- During titration, the individual may experience orthostatic hypotension and should change positions slowly.
- Do not abruptly discontinue.

BID, twice a day; CNS, central nervous system; OTC, over the counter.

BOX 24.9

Drug Profile: Clozapine (Clozaril)

DRUG CLASS: Atypical antipsychotic

RECEPTOR AFFINITY: D1 and D2 blockade, antagonist for 5-HT₂, histamine (H₁), α -adrenergic, and acetylcholine. These additional antagonist effects may contribute to some of its therapeutic effects. Produces fewer extrapyramidal effects than standard antipsychotics with lower risk for tardive dyskinesia.

INDICATIONS: Severely ill individuals who have schizophrenia and have not responded to standard antipsychotic treatment; reduction in risk of recurrent suicidal behavior in schizophrenia or SADs.

ROUTES AND DOSAGE: Available only in tablet form, 25- and 100-mg doses.

Adult Dosage: Initial dose 25 mg PO twice or four times daily, may gradually increase in 25 to 50 mg/day increments, if tolerated, to a dose of 300 to 450 mg/day by the end of the second week. Additional increases should occur no more than once or twice weekly. Do not exceed 900 mg/day. For maintenance, reduce dosage to lowest effective level.

Children: Safety and efficacy with children younger than age 16 years have not been established.

HALF-LIFE (PEAK EFFECT): 12 h (1 to 6 h)

SELECT ADVERSE REACTIONS: Drowsiness, dizziness, headache, hypersalivation, tachycardia, hypo- or hypertension, constipation, dry mouth, heartburn, nausea or vomiting, blurred vision, diaphoresis, fever, weight gain, hematologic changes, seizures, tremor, akathisia

BOXED WARNING: Agranulocytosis, defined as a granulocyte count of $<500 \text{ mm}^3$, occurs at about a cumulative 1-year incidence of 1.3%, most often within 4 to 10 weeks of exposure, but may occur at any time; WBC count before initiation, and weekly WBC counts while taking the drug and for 4 weeks after discontinuation. Seizures, myocarditis, and other adverse cardiovascular and respiratory side effects (i.e., orthostatic hypotension).

WARNING: Increased mortality in older patients with dementia-related psychosis; rare development of NMS; *hyperglycemia and DM*, *tardive dyskinesia*, cases of sudden, unexplained death have been reported; avoid use during pregnancy and while breast feeding.

PRECAUTIONS: Fever, pulmonary embolism, hepatitis, anticholinergic toxicity, and interference with cognitive and motor functions.

SPECIFIC PATIENT/FAMILY EDUCATION

- Need informed consent regarding risk for agranulocytosis. Weekly or biweekly blood draws are required. Notify your prescriber immediately if lethargy, weakness, sore throat, malaise, or other flu-like symptoms develop.
- You should not take clozapine if you are taking other medicines that may cause the same serious bone marrow side effects.
- Inform the patient of risk of seizures, hyperglycemia and diabetes, and orthostatic hypotension. It may potentiate the hypotensive effects of antihypertensive drugs and anticholinergic effects of atropine-like drugs.
- Administration of epinephrine should be avoided in the treatment of drug-induced hypotension.
- Notify your prescriber if pregnancy is possible or if you are planning to become pregnant. Do not breastfeed while taking this medication.
- Notify your prescriber before taking any other prescription or OTC medication. Avoid alcohol or other CNS depressant drugs.
- May cause drowsiness and seizures; avoid driving or other hazardous tasks.
- During titration, the individual may experience orthostatic hypotension and so should change positions slowly.
- Do not abruptly discontinue.

CNS, central nervous system; NMS, neuroleptic malignant syndrome; OTC, over-the-counter; WBC, white blood cell.

BOX 24.10

Research for Evidence-Based Practice: Families and Medication Use and Adherence among Latinos

Hernandez, M. & Barrio, C. (2017). Families and medication use and adherence among Latinos with

schizophrenia. *Journal of Mental Health*, 26(1), 14–20.

THE QUESTION: What are the perceptions of treatment related to medication use among Latinos with schizophrenia and key family members?

METHODS: Purposive sampling was used to collect data from a total of 34 participants: 14 dyads (made up of 14 patients and 14 key family members) plus 6 key family members of other patients. These six family members, who were interviewed although the patient was not available, were included to provide additional information about family context. Semistructured interviews were conducted with participants in their preferred language.

FINDINGS: Concerns primarily centered on medication side effects. Patients expressed difficulty with low energy, lack of interest in desired activities, and weight gain, among other issues. Family members also noticed changes in patients' affect and behavior. Moreover, families worried about long-term medication use and its effect on patients' health.

IMPLICATIONS FOR NURSING: Family involvement in medication use is important and contributes to patient choices regarding treatment.

Monitoring Extrapyramidal Side Effects

Parkinsonism caused by antipsychotic drugs is identical in appearance to Parkinson disease and tends to occur in older patients. The symptoms are believed to be caused by the blockade of dopamine D₂ receptors in the basal ganglia, which throws off the normal balance between acetylcholine and dopamine in this area of the brain and effectively increases acetylcholine transmission. The symptoms are managed by reducing dosage and thereby increasing dopamine activity or adding an anticholinergic drug, thus decreasing acetylcholine activity, such as benztropine or trihexyphenidyl.

Dystonic reactions are also believed to result from the imbalance of dopamine and acetylcholine, with the latter dominant. Young men seem to be more vulnerable to this particular extrapyramidal side effect. This side effect, which develops rapidly and dramatically, can be very frightening for patients as their muscles tense and their body contorts. The experience often starts with **oculogyric crisis**, in which the muscles that control eye movements tense and pull the eyeball so that the patient is looking toward the ceiling. This may be followed rapidly by **torticollis**, in which the neck muscles pull the head to the side, or **retrocollis**, in which the head is pulled back, or orolaryngeal–pharyngeal hypertonus, in which the patient has extreme difficulty in swallowing. The patient may also experience contorted limbs. These symptoms occur early in

antipsychotic drug treatment, when the patient may still be enduring psychotic symptoms, which compounds the patient's fear and anxiety and requires a quick response. The immediate treatment is to administer benztropine 1 to 2 mg, or diphenhydramine (Benadryl), 25 to 50 mg, intramuscularly or intravenously. This is followed by daily administration of anticholinergic drugs and, possibly, by a decrease in dosage antipsychotic medication. See [Box 24.11](#) for more information about benztropine.

Akathisia appears to be caused by the same biologic mechanism as other **extrapyramidal side effects**. Patients are restless and report they feel driven to keep moving. They are extremely uncomfortable. Frequently, this response is misinterpreted as anxiety or increased psychotic symptoms, so that the patient may inappropriately be given increased dosages of an antipsychotic drug, which only perpetuates the side effect. If possible, the dose of antipsychotic drug should be reduced. A beta-adrenergic blocker such as propranolol (Inderal), 20 to 120 mg, may be required. An anticholinergic medication may not be helpful. Failure to manage this side effect is a leading cause of patients ceasing to take antipsychotic medications (see [Chapter 12](#)).

Tardive dyskinesia, *tardive dystonia*, and *tardive akathisia* are less likely but still possible to appear in individuals taking second-generation, rather than first-generation, antipsychotics. [Table 24.2](#) describes these and associated motor abnormalities. The term *tardive* means late-appearing, thus all of these movements appear after a person has taken these drugs for a period of time. Thus, tardive dyskinesia is late-appearing abnormal involuntary movements. It can be viewed as the opposite of parkinsonism, both in observable movements and in etiology. Whereas muscle rigidity and absence of movement characterize parkinsonism, constant movement characterizes tardive dyskinesia. Typical movements involve the mouth, tongue, and jaw and include lip smacking, sucking, puckering, tongue protrusion, the “bonbon sign” (where the tongue rolls around in the mouth and protrudes into the cheek as if the patient is sucking on a piece of hard candy), athetoid (worm-like) movements of the tongue and chewing. Other facial movements, such as grimacing and eye blinking, may also be present.

BOX 24.11

Drug Profile: Benztropine Mesylate

DRUG CLASS: Antiparkinsonism agent

RECEPTOR AFFINITY: Blocks cholinergic (acetylcholine) activity, which is believed to restore the balance of acetylcholine and dopamine in the basal ganglia.

INDICATIONS: Used in psychiatry to reduce extrapyramidal symptoms (acute medication-related movement disorders), including pseudoparkinsonism, dystonia, and akathisia (but not tardive syndromes) caused by neuroleptic drugs such as haloperidol. Most effective with acute dystonia.

ROUTES AND DOSAGE: Available in tablet form, 0.5-, 1-, and 2-mg doses, also injectable 1 mg/mL

Adult Dosage: For acute dystonia, 1 to 2 mg IM or IV usually provides rapid relief. No significant difference in onset of action after IM or IV injection. Treatment of emergent symptoms may be relieved in 1 or 2 days, with 1 to 2 mg PO two to three times a day. Maximum daily dose is 6 mg/day. After 1–2 weeks, withdraw drug to see if continued treatment is needed. Medication-related movement disorders that develop slowly may not respond to this treatment.

Geriatric: Older adults and very thin patients cannot tolerate large doses.

Children: Do not use in children younger than 3 years of age. Use with caution in older children.

HALF-LIFE: 12 to 24 hours; very little pharmacokinetic information is available.

SELECT SIDE EFFECTS: Dry mouth, blurred vision, tachycardia, nausea, constipation, flushing or elevated temperature, decreased sweating, muscular weakness or cramping, urinary retention, urinary hesitancy, dizziness, headache, disorientation, confusion, memory loss, hallucinations, psychoses, and agitation in toxic reactions, which are more pronounced in older adults and occur at smaller doses

WARNING: Avoid use during pregnancy and while breastfeeding. Give with caution in hot weather because of possible heatstroke. Contraindicated with angle-closure glaucoma, pyloric or duodenal obstruction, stenosing peptic ulcers, prostatic hypertrophy or bladder neck obstructions, myasthenia gravis, megacolon, and megaesophagus. May aggravate the symptoms of tardive dyskinesia and other chronic forms of medication-related movement disorder. Concomitant use of other anticholinergic drugs may increase side effects and risk for toxicity. Coadministration of haloperidol or phenothiazines may reduce serum levels of these drugs.

SPECIFIC PATIENT/FAMILY EDUCATION

- Take with meals to reduce dry mouth and gastric irritation.
- Dry mouth may also be alleviated by sucking sugarless candies, maintaining adequate fluid intake, and good oral hygiene; increase fiber and fluids in diet to avoid constipation; stool softeners may be required. Notify your prescriber if urinary hesitancy or constipation persists.
- Notify your prescriber if rapid or pounding heartbeat, confusion, eye pain, rash, or other side effects develop.
- May cause drowsiness, dizziness, or blurred vision; use caution driving or performing other hazardous tasks requiring alertness. Avoid alcohol and other CNS depressants.
- Do not abruptly stop this medication because a flu-like syndrome may develop.
- Use with caution in hot weather. Ensure adequate hydration. May increase susceptibility to heat stroke.

CNS, central nervous system; IM, intramuscular; IV, intravenous; PO, oral.

TABLE 24-2: Extrapyramidal Side Effects of Antipsychotic Drugs

Side Effect	Period of Onset	Symptoms
Acute Motor Abnormalities		
Parkinsonism or pseudoparkinsonism	5–30 d	Resting tremor, rigidity, bradykinesia or akinesia, masklike face, shuffling gait, decreased arm swing
Acute dystonia	1–5 d	Intermittent or fixed abnormal postures of the eyes, face, tongue, neck, trunk, and limbs
Akathisia	1–30 d	Obvious motor restlessness evidenced by pacing, rocking, shifting from foot to foot; subjective sense of not being able to sit or be still; these symptoms may occur together or separately
Late-Appearing Motor Abnormalities		
Tardive dyskinesia	Months to years	Abnormal dyskinetic movements of the face, mouth, and jaw; choreoathetoid movements of the legs, arms, and trunk
Tardive dystonia	Months to years	Persistent sustained abnormal postures in the face, eyes, tongue, neck, trunk, and limbs
Tardive akathisia	Months to years	Persistent unabating sense of subjective and objective restlessness

Adapted from Levenson, J.L., Crouse, E.L., & Bozyski, K.M. (2019). Psychopharmacology. In L.W. Roberts, (Eds.), *The American psychiatric publishing textbook of psychiatry* (7th ed.). American Psychiatric Association.

Movements in the trunk and limbs are frequently observable with tardive dyskinesia. These include rocking from the hips, athetoid movements of the fingers and toes, jerking movements of the fingers and toes, guitar-strumming movements of the fingers, and foot tapping. The long-term health problems for people with tardive dyskinesia are choking, associated with loss of control of muscles used for swallowing, and compromised respiratory function, leading to

infections and possibly respiratory alkalosis.

Because the movements resemble the dyskinetic movements of some patients who have idiopathic Parkinson disease and who have received long-term treatment with L-DOPA (a direct-acting dopamine agonist that crosses the blood–brain barrier), the suggested hypothesis for tardive dyskinesia includes the supersensitivity of the dopamine receptors in the basal ganglia.

An effective treatment for tardive dyskinesia has been elusive. However, antipsychotic drugs mask the movements of tardive dyskinesia and have periodically been suggested as a treatment. This is counterintuitive because these drugs cause the disorder. Second-generation antipsychotic drugs, such as clozapine, may be less likely to cause it; however, recent interest suggests that the tardive dyskinesia is still prevalent but at a lesser rate (Misdrahi et al., 2019). Recently the medications deutetrabenazine and valbenazine have been approved by the U.S. Food and Drug Administration (FDA) and appear to ameliorate the movements of tardive dyskinesia by decreasing the transport of dopamine into storage vesicles (via inhibition of vesicular monoamine transporter 2—VMAT2) and therefore reducing the overall availability of dopamine (Ricciardi et al., 2019). However, the best management remains prevention through using the lowest possible dose of an antipsychotic drug over time that minimizes the symptoms of schizophrenia as well as regular evaluation of movements using tools like the DISCUS (see [Box 24.4](#)).

Monitoring Other Side Effects

Orthostatic hypotension is a common side effect of antipsychotic drugs. Primarily an antiadrenergic effect, decreased blood pressure may be generalized or orthostatic. Patients may be protected from falls by teaching them to rise slowly and by monitoring blood pressure before giving the medication. The nurse should monitor and document lying, sitting, and standing blood pressures when any antipsychotic drug therapy begins.

Hyperprolactinemia can occur. When dopamine is blocked in the tuberoinfundibular tract, it can no longer repress prolactin, the neurohormone that regulates lactation and mammary function. The prolactin level increases and, in some individuals, side effects appear. Gynecomastia (i.e., enlarged breasts) can occur in people of both sexes and is understandably distressing to individuals who may be experiencing delusional or hallucinatory body image

disturbances. Galactorrhea (i.e., lactation) may also occur. Menstrual irregularities and sexual dysfunction are possible. If these symptoms appear, the medication should be reduced or changed to another antipsychotic agent. Hyperprolactinemia is associated with the use of haloperidol and risperidone.

Sedation is another possible side effect of antipsychotic medication and a frequent reason that patients discontinue medications. Patients should be monitored for the sedating effects of antipsychotic agents. In older patients, sedation can be associated with falls.

Weight gain is related to antipsychotic agents, especially olanzapine and clozapine. Patients may gain as much as 20 or 30 pounds within 1 year. Such increased appetite and weight gain are distressing to patients. Diet teaching and monitoring may have some effect. Another solution is to increase the accessibility of healthful easy-to-prepare food. Simple exercise routines may be helpful.

New-onset DM should be assessed in patients taking antipsychotic drugs. An association has been found between new-onset DM and the administration of second-generation antipsychotic agents, especially after weight gain. Patients should be monitored for clinical symptoms of diabetes. Fasting blood glucose tests and Hemoglobin A1C monitoring are commonly ordered for these individuals.

Cardiac arrhythmias may also occur. Prolongation of the QTc interval is associated with torsade de pointe (polymorphic ventricular tachycardia) or ventricular fibrillation. The potential for drug-induced prolonged QT interval is associated with many drugs. Ziprasidone (Geodon) is more likely than other second-generation antipsychotics to prolong the QT interval and thus change the heart rhythm. For these patients, baseline electrocardiograms may be ordered. Nurses should observe these patients for cardiac arrhythmias.

Agranulocytosis is a reduction in the number of circulating granulocytes and decreased production of granulocytes in the bone marrow, which limits one's ability to fight infection. Agranulocytosis can develop with the use of all antipsychotic drugs, but it is most likely to develop with clozapine use. Although laboratory values below 500 cells/mm³ are indicative of agranulocytosis, often granulocyte counts drop to below 200 cells/mm³ with this syndrome.

Patients taking clozapine should have regular blood tests. White blood cell and granulocyte counts should be measured before treatment is initiated and at least weekly or twice weekly after treatment begins. Initial white blood cell

counts should be above 3,500 cells/mm³ before treatment initiation; in patients with counts of 3,500 and 5,000 cells/mm³, cell counts should be monitored three times a week if clozapine is prescribed. Any time the white blood cell count drops below 3,500 cells/mm³ or granulocytes drop below 1,500 cells/mm³, use of clozapine should be stopped, and the patient should be monitored for infection.

However, a faithfully implemented program of blood monitoring should not replace careful observation of the patient. It is not unusual for blood cell counts to drop precipitously over a period of 2 to 3 days. This may not be discovered when the patient is on a strict weekly blood monitoring schedule. Any reported symptoms that suggest a bacterial infection (e.g., fever, pharyngitis, weakness) should be cause for concern, so immediate evaluation of blood count status should be undertaken. Because patients are frequently discharged before the critical period of risk for agranulocytosis, patient education about these symptoms is also essential so that they will report these symptoms, obtain blood monitoring, and reduce their potential exposure to infections. In general, granulocyte levels return to normal within 2 to 4 weeks after discontinuation of use of the medication.

DRESS is a very rare, potentially life-threatening, drug-induced hypersensitivity reaction recently associated with ziprasidone therapy (Geodon). The FDA published a safety announcement related to ziprasidone's association to DRESS. Symptoms include skin eruption, hematologic abnormalities (e.g., eosinophilia, atypical lymphocytosis), lymphadenopathy, and internal organ involvement (e.g., liver, kidney, lung). DRESS has a mortality rate of 10% (U.S. Food and Drug Administration, 2015).

Preventing Drug–Drug Interactions

Antipsychotic medications have the potential to interact with other medications, nicotine, and grapefruit juice. For example, olanzapine and clozapine have the potential to interact with some antidepressants. Some antipsychotics are metabolized faster in smokers than nonsmokers (Chui et al., 2019). Conversely, problems with increased side effects from slower drug metabolism can occur when smoking cessation programs are initiated. Before giving medication, the nurse should check all medications for potential interactions.

Teaching Points

Nonadherence to the medication regimen is an important factor in relapse; the family must be made aware of the importance of the patient's taking medications consistently. Medication education should cover the association between medications and the amelioration of symptoms, side effects, and their management, and interpersonal skills that help the patient and family report medication effects.

Management of Complications

Neuroleptic Malignant Syndrome

Neuroleptic malignant syndrome (NMS) is a life-threatening condition that can develop in reaction to antipsychotic medications. The primary symptoms of NMS are *mental status changes*, *severe muscle rigidity*, and *autonomic changes*, including elevated temperature (usually between 101°F and 103°F), tachycardia, and blood pressure lability. Mental status changes and severe muscle rigidity occur usually within the first week of initiation of antipsychotic therapy and can include two or more of the following: hypertension, tachycardia, tachypnea, prominent diaphoresis, incontinence, mutism, leukocytosis, and laboratory evidence of muscle injury (e.g., elevated creatinine phosphokinase). The incidence of NMS has decreased from 3% to 0.16%, probably because of increased awareness of symptoms, use of atypical antipsychotics, and earlier interventions, such as stopping the offending medication (Schneider et al., 2018). As many as 5% to 15% of affected patients may die as a result of the syndrome. In the past, NMS was probably underreported and may have accounted for unexplained emergency department deaths of patients taking these drugs because their symptoms did not seem serious.

The most important aspects of nursing care for patients with NMS relate to recognizing symptoms early, withholding any antipsychotic or any other dopamine antagonist (e.g., gastric reflux medications), and initiating supportive nursing care (Fig. 24.4). In any patient with muscle rigidity, fluctuating vital signs, abrupt changes in levels of consciousness, or any of the symptoms presented in Box 24.12, NMS should be suspected. The nurse should be

especially alert for early signs and symptoms of NMS in high-risk patients, such as those who are agitated, physically exhausted, or dehydrated or who have an existing medical or neurologic illness. Patients receiving parenteral or higher doses of neuroleptic drugs or lithium concurrently must also be carefully assessed. The nurse should carefully monitor fluid intake, and fluid and electrolyte status.

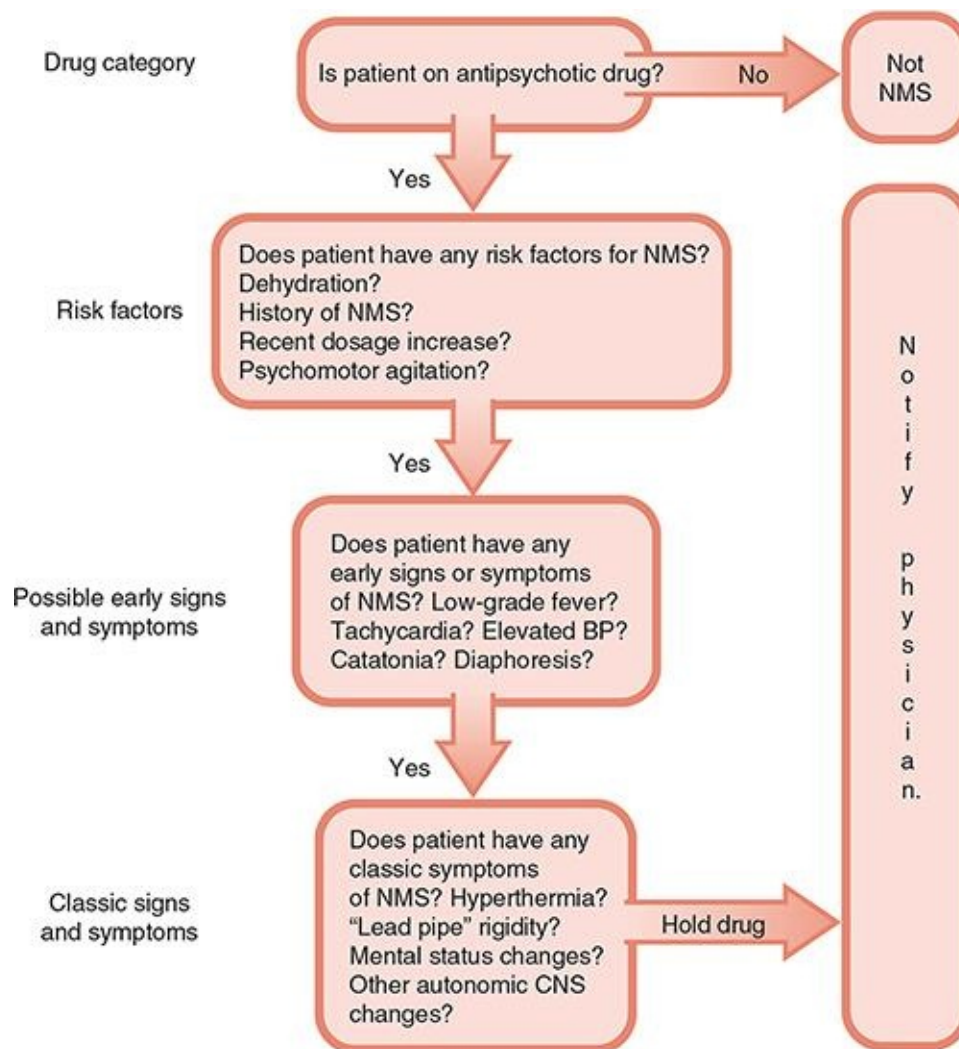

FIGURE 24-4: Action tree for “holding” an antipsychotic drug because of suspected neuroleptic malignant syndrome. BP, blood pressure; CNS, central nervous system; NMS, neuroleptic malignant syndrome.

BOX 24.12

Recognizing Neuroleptic Malignant Syndrome

Onset: 2 weeks after initiation of antipsychotic treatment or change in dosage

Risk factors: Male gender, preexisting medical or neurologic disorders, depot injection administration, and high ambient temperature

IMMINENT INDICATORS

- Mental status changes
- Muscle rigidity
- Hyperthermia
- Tachycardia
- Hypertension or hypotension
- Tachypnea or hypoxia
- Diaphoresis or sialorrhea
- Tremor
- Incontinence
- Creatinine phosphokinase elevation or myoglobinuria
- Leukocytosis
- Metabolic acidosis

Source: Neuroleptic malignant syndrome. Retrieved on February 20, 2021 from <https://rarediseases.org/rare-diseases/neuroleptic-malignant-syndrome/>

NCLEXNOTE Recognition of side effects, including movement disorders, tardive dyskinesia, and weight gain, should lead to interventions. NMS is a medical emergency.

Medical treatment focuses on symptom management and includes administering dopamine agonist drugs, such as bromocriptine (modest success), and muscle relaxants, such as dantrolene or benzodiazepine. Antiparkinsonism drugs are not particularly useful. Some patients experience improvement with electroconvulsive therapy (ECT).

The nurse must frequently monitor vital signs of the patient with symptoms of NMS. In addition, it is important to check the results of the patient's laboratory tests for increased creatine phosphokinase, an elevated white blood cell count, elevated liver enzymes, or myoglobinuria. The nurse must be prepared to initiate supportive measures or anticipate emergency transfer of the patient to a medical-surgical or an intensive care unit.

Treating fever (which frequently exceeds 103°F) is an important priority for these patients. High body temperature may be reduced with a cooling blanket and acetaminophen therapy. Because many of these patients experience diaphoresis, temperature elevation, or dysphagia, it is important to monitor hydration. Another important aspect of care for patients with NMS is safety.

Joints and extremities that are rigid or spastic must be protected from injury. The treatment of these patients depends on the facility and availability of medical support services. In general, patients in psychiatric inpatient units that are separated from general hospitals are transferred to medical-surgical settings for treatment.

Cholinergic Rebound

If patients are prescribed an anticholinergic agent, such as benztropine, for movement disorders and they abruptly stop taking it, they could experience **cholinergic rebound** symptoms including vomiting, excessive sweating, and altered dreams and nightmares. Cholinergic rebound can be especially problematic if patients discontinue other medications with anticholinergic properties (e.g., antipsychotics, antidepressants, antibiotics) at the same time. Medications with anticholinergic properties should be reduced gradually (tapered) over several days. [Table 24.3](#) lists anticholinergic side effects and several antipsychotic medications and interventions to manage them.

TABLE 24-3: NURSING INTERVENTIONS FOR ANTICHOLINERGIC SIDE EFFECTS

Effect	Intervention
Dry mouth	Provide sips of water, hard candies, and chewing gum (preferably sugar free).
Blurred vision	Avoid dangerous tasks; teach patient that this side effect will diminish in a few weeks.
Decreased lacrimation	Use artificial tears if necessary.
Mydriasis	May aggravate glaucoma; teach patient to report eye pain.
Photophobia	Wear sunglasses.
Constipation	High-fiber diet; increased fluid intake; take laxatives as prescribed.
Urinary hesitancy	Privacy; run water in sink; warm water over perineum
Urinary retention	Regular voiding (at least every 2–3 h) and whenever urge is present; catheterize for residual urine; record intake and output; evaluate for

benign prostatic hypertrophy.
Tachycardia Evaluate for preexisting cardiovascular disease.

Anticholinergic Medication Effects and Abuse

The potential exists for abuse of anticholinergic drugs. Some patients may find the anticholinergic effects of these drugs on mood, memory, and perception pleasurable. Although at toxic dosages, patients may experience a mild delirium with disorientation and hallucinations, lesser doses may cause patients to experience greater sociability and euphoria.

Anticholinergic Crisis

An **anticholinergic crisis** is a potentially life-threatening medical emergency caused by an overdose of or sensitivity to drugs with anticholinergic properties. This syndrome (also called anticholinergic delirium) may result from an accidental or intentional overdose of anticholinergic drugs, including atropine, scopolamine, or belladonna alkaloids, which are present in numerous prescription drugs and OTC medicines. The syndrome may also occur in psychiatric patients who are not only receiving therapeutic doses of anticholinergic drugs but also taking other drugs with anticholinergic properties. As a result of either drug overdose or sensitivity, these anticholinergic substances may produce acute delirium or a psychotic reaction resembling schizophrenia. Severe anticholinergic effects may occur in older patients, even at therapeutic levels (Pasina et al., 2019).

The signs and symptoms of anticholinergic crisis are dramatic and physically uncomfortable (Box 24.13). This disorder is characterized by fever, parched mouth, burning thirst, hot dry skin, decreased salivation, decreased bronchial and nasal secretions, widely dilated eyes (bright light becomes painful), decreased ability to accommodate visually, increased heart rate, constipation, difficulty urinating, and hypertension or hypotension. The face, neck, and upper arms may become flushed because of reflexive blood vessel dilation. In addition to peripheral symptoms, patients with anticholinergic psychosis may experience neuropsychiatric symptoms of anxiety, agitation, delirium, hyperactivity,

confusion, hallucinations (especially visual), speech difficulties, psychotic symptoms, or seizures. The acute psychotic reaction that is produced resembles schizophrenia. The classic description of anticholinergic crisis is summarized in the following mnemonic: “Hot as a hare, blind as a bat, mad as a hatter, dry as a bone.”

In general, episodes of anticholinergic crisis are self-limiting, usually subsiding in 3 days. However, if left untreated, the associated fever and delirium may progress to coma or cardiac and respiratory depression. Although rare, death is generally caused by hyperpyrexia and brain stem depression. After use of the offending drug is discontinued, improvement usually occurs within 24 to 36 hours.

BOX 24.13

Signs and Symptoms of Anticholinergic Crisis

- **Neuropsychiatric signs:** confusion; recent memory loss; agitation; dysarthria; incoherent speech; pressured speech; delusions; ataxia; periods of hyperactivity alternating with somnolence, paranoia, anxiety, or coma
- **Hallucinations:** accompanied by “picking,” plucking, or grasping motions; delusions; or disorientation
- **Physical signs:** nonreactive dilated pupils; blurred vision; hot, dry, flushed skin; facial flushing; dry mucous membranes; difficulty swallowing; fever; tachycardia; hypertension; decreased bowel sounds; urinary retention; nausea; vomiting; seizures; or coma

A specific and effective antidote, physostigmine, a reversible inhibitor of cholinesterase, is frequently used to treat and diagnose anticholinergic crisis. Administration of this drug rapidly reduces both behavioral and physiologic symptoms. However, the usual adult dose of physostigmine is 1 to 2 mg, intravenously given slowly during a period of 5 minutes because rapid injection of physostigmine may cause seizures, profound bradycardia, or heart block. Physostigmine is relatively short acting, so it may need to be given several times during the course of treatment. This drug provides relief from symptoms for a period of 2 to 3 hours. In addition to receiving physostigmine, patients who intentionally overdose on large amounts of anticholinergic drugs are treated by gastric lavage, administration of charcoal, and catharsis. The dose may be given again after 20 or 30 minutes.

It is important for the nurse to be alert for signs and symptoms of anticholinergic crisis, especially in older and pediatric patients, who are much

more sensitive to the anticholinergic effects of drugs, and in patients who are receiving multiple medications with anticholinergic effects. If signs and symptoms of the syndrome occur, the nurse should discontinue use of the offending drug and notify the physician immediately.

Electroconvulsive Therapy

ECT is suggested as a possible alternative when the patient's schizophrenia is not being successfully treated by medication alone. For the most part, this modality is not indicated unless the patient is catatonic or has depression that is not treatable by other means. In general, ECT is not used often for the treatment of schizophrenia, but it may be useful for those persons who are medication resistant, assaultive, and psychotic (Kellner et al., 2020).

Psychosocial Interventions

Psychosocial interventions, such as counseling, conflict resolution, behavior therapy, and cognitive interventions, are appropriate for patients with schizophrenia. The following discussion focuses on applying these interventions.

Therapeutic Interactions

Although antipsychotic medications may relieve positive symptoms, they do not always eliminate hallucinations and delusions. The nurse must continue helping the patient develop creative strategies for dealing with these sensory and thought disturbances. Information about the content of the hallucinations and delusions is necessary, not only to determine whether the medications are effective but also to assess safety and the meaning of these thoughts and perceptions to the patient. In caring for a patient who is experiencing hallucinations or delusions, nursing actions should be guided by three general patient outcomes:

- Decrease the frequency and intensity of hallucinations and delusions.
- Recognize that hallucinations and delusions are symptoms of a brain disorder.
- Develop strategies to manage the recurrence of hallucinations or delusions.

When interacting with a patient who is experiencing hallucinations or delusions, the nurse must remember that these experiences are real to the patient. It is important for the nurse to understand the content and meaning of the hallucinations, particularly those involving command hallucinations.

On the one hand, the nurse should never tell a patient that these experiences are not real. Discounting the experiences blocks communication. On the other hand, it is also dishonest for the nurse to tell the patient that the nurse is having the same hallucinatory experience. It is best to validate the patient's experiences and identify the meaning of these thoughts and feelings to the patient. For example, a patient who believes that they are under surveillance by the Federal Bureau of Investigation probably feels frightened and suspicious of everyone. By acknowledging how frightening it must be to always feel like you are being watched, the nurse focuses on the feelings that are generated by the delusion, not the delusion itself. The nurse can then offer to help the patient feel safe within this environment. The patient, in turn, begins to feel that someone understands them.

Enhancing Cognitive Functioning

After identifying deficits in cognitive functioning, the nurse and patient can develop interventions that target specific deficits. The most effective interventions usually involve the whole treatment team. If the ability to focus or maintain attention is an issue, patients can be encouraged to select activities that improve attention, such as computer games. For memory problems, patients can be encouraged to make lists and to write down important information.

Executive functioning problems are the most challenging for these patients. Patients who cannot manage daily problems may have planning and problem-solving impairments. For these patients, developing interventions that closely simulate real-world problems may help. Through coaching, the nurse can teach and support the development of problem-solving skills. For example, during hospitalizations, patients are given medications and reminded to take them on time. They are often instructed in a classroom setting but rarely have an opportunity to practice self-medication and figure out what to do if their prescription expires, the medications are lost, or they forget to take their medications. Even so, when discharged, patients are expected to take medication at the prescribed dose at the prescribed time. Interventions designed to have

patients actively engage in problem-solving behavior with real problems are needed.

Other approaches to helping patients solve problems and learn new strategies for dealing with problems include solution-focused therapy, which focuses on the strengths and positive attributes that exist within each person, and cognitive-behavioral therapy (Jones et al., 2019), which focuses directly on collaboratively determined symptoms and strategies to address them. These therapies involve years of training to master, but certain techniques can be used. For example, the nurse can ask patients to identify the most important problem from their perspective. This focuses the patient on an important issue for them.

Using Behavioral Interventions

Behavioral interventions can be very effective in helping patients improve motivation and organize routine, daily activities, such as maintaining a regular schedule and completing activities. Reinforcement of positive behaviors (getting up on time, completing hygiene, going to treatment activities) can easily be included in a treatment plan. In the hospital, patients gain unit privileges by following an agreed-on treatment plan. In the community, a behavioral intervention is more likely to be combined with other approaches or used for a specific behavior such as smoking (Wilson et al., 2019).

Psychoeducation

Teaching Strategies

Cognitive deficits (e.g., difficulty in processing complex information, maintaining steady focus of attention, distinguishing between relevant and irrelevant stimuli, and forming abstractions) may challenge the nurse planning educational activities. Evidence indicates that people with schizophrenia may learn best in an errorless learning environment (Kern et al., 2018). That is, they are directly given correct information and then encouraged to write it down. Errorless learning is an educational intervention based on the principle of operant conditioning that learning is stronger and more likely to last if it occurs in the absence of errors. Asking questions that encourage guessing is not as

effective in helping patients retain information. Trial-and-error learning is avoided.

Teaching and explaining should occur in an environment with minimal distractions. Terminology should be clear and unambiguous. Visual aids can supplement verbal information, but these materials should have simple information stated in simple language. The nurse takes care not to overcrowd the visual material or incorporate images that draw attention away from important content. Teaching should occur in small segments with frequent reinforcement. Most importantly, teaching should occur when the patient is ready. Regular assessments of cognitive abilities with standardized instruments can help determine this readiness. These suggestions can be adapted for teaching during any phase of the illness.

Teaching About Symptoms

Teaching patients that hallucinations and delusions are part of the disorder becomes easier after the medication begins working. When patients believe and acknowledge that they have a mental illness and that some of their thoughts are delusions and some of their perceptions are hallucinations, they can develop strategies to manage their symptoms.

Patients benefit greatly by learning recovery strategies of self-regulation, symptom monitoring, and relapse prevention. By monitoring events, time, place, and stimuli surrounding the appearance of symptoms, the patient can begin to predict high-risk times for symptom recurrence. Cognitive-behavioral therapy is often used in helping patients monitor and identify their emerging symptoms to prevent relapse (Liu et al., 2019b).

Another important nursing intervention is to help the patient identify to whom and where to talk about delusional or hallucinatory material. Because self-disclosure of these symptoms immediately labels someone as having a mental illness, patients should be encouraged to evaluate the environment for negative consequences of disclosing these symptoms. For example, it may be fine to talk about it at home but not at the grocery store.

Teaching How to Cope With Stress

Developing skills to cope with personal, social, and environmental stresses is important to everyone but particularly to those with a severe mental illness. Stresses can easily trigger symptoms that patients are trying to avoid. Establishing regular counseling sessions to support the development of positive coping skills is helpful for both hospitalized patients and those living in the community.

Wellness Strategies

Wellness strategies require providers to consider multiple aspects of what is considered a well-lived life. As with recovery, it is important to establish what “living well with mental illness” means to the individual with schizophrenia. Within the limitations of the illness and its treatment, providers need to work with the person to define wellness. Wellness should be defined beyond just the best physical health possible and includes positive social relationships, engaging leisure and work activities, and spiritual connections, to name a few. To varying degrees, evidence supports interventions such as (1) cognitive training and remediation that focus on cognitive impairments and social functioning (Miley et al., 2020) and could incorporate new methodologies that use virtual reality (Souto et al., 2020); (2) support that provides information about the illness, addresses emotional needs, acknowledges the challenges of the illness, encourages the person, and provides guidance (Beentjes et al., 2020); and (3) goal setting with the individual that uses methodologies like the “Choose-Get-Keep” model that supports client goals over the imposition of provider goals (Anthony et al., 2014).

Social Skills Training

Social skills training, provided either individually or in groups, is also useful when working with patients who have schizophrenia (Vogel et al., 2019). This training teaches patients specific behaviors needed for social interactions. The

skills are taught by lecture, demonstration, role-playing, and homework assignments. Nurses may be team members and be involved in case management or provision of services. Furthermore, efforts to offer supportive employment experiences (Carmona et al., 2019) that incorporate patient preferences, rapid job search and employment, and ongoing job supports have shown effectiveness. Although long-term self-sufficiency has not necessarily been achieved, supportive employment has been the most effective vocational rehabilitation method.

Skill-training interventions should be designed to compensate for cognitive deficits. To help patients learn to process complex activities, such as catching a bus, preparing a meal, or shopping for food or clothing, nurses should break the activity into small parts or steps and list them for the patient's reference, for example:

- Leave your apartment with your keys in hand.
- Make sure you have correct bus fare in your pocket.
- Close the door.
- Walk to the corner.
- Turn right and walk three blocks to the bus stop.

Concept Mastery Alert

If the patient has active psychosis, with symptoms such as hallucinations and social withdrawal, wait until a lucid period to begin social skills training. When a patient is in active psychosis, it is not a good time to introduce additional stressors.

Providing Family Education

Because having a family member with schizophrenia is a life-changing event for the family and friends who provide care and support, educating patients and their families is crucial. It is a primary concern for the psychiatric–mental health nurse. Family support is crucial to help patients maintain treatment. Education should include information about the disease course, treatment regimens, support systems, and life management skills (Box 24.14). The most important factor to stress during patient and family education is the consistent taking of medication.

Promoting Safety

Although violence is not a consistent behavior of people with schizophrenia, it is always a concern during the initial phase when hallucinations or delusions may put patients at risk for harming themselves or others. Nonviolent patients who are experiencing hallucinations and delusions can also be at risk for victimization by more aggressive patients. The patient who is hallucinating needs to be protected; this may include increased staff monitoring and, if necessary, a safer environment in a secluded area.

BOX 24.14

Psychoeducation Checklist: Schizophrenia

When caring for the patient with schizophrenia, be sure to include the caregiver during planning as appropriate and address the following topic areas in the teaching plan:

- Psychopharmacologic agents, including drug action, dosage, frequency, and possible side effects; stress the importance of adherence to the prescribed regimen
- Management of hallucinations
- Recovery strategies
- Coping strategies (e.g., self-talk, getting busy with something)
- Management of the environment
- Community resources

Identifying patient risk factors for violence, such as a history of violence can alert the nursing staff of a potential for engaging in aggressive behavior, but careful assessment and management of the immediate environment and treating the psychiatric symptoms are more important in avoiding aggression. The nurse's best approach to avoiding violence or aggression is to demonstrate respect for the patient and the patient's personal space, assess and monitor for signs of fear and agitation, and use preventive interventions before the patient loses control. Patients should be encouraged to discuss their anger and to be involved in their treatment decisions. Medications should be administered as ordered. Because most antipsychotic and antidepressant medications take 1 to 2 weeks to begin moderating behavior, the nurse must be vigilant during the acute illness.

If the patient loses control and is a danger to self or others, restraints and

seclusion may be used as a last resort. Health Care Financing Administration guidelines and hospital policy must be followed (see [Chapter 4](#)), and staff should be trained in the proper use of seclusion and restraints. In addition, staff need to have planned sessions after all incidents of violence or physical management to analyze the event. These sessions allow clinicians to learn how better to manage these situations and evaluate patients' cues. With sensitive leadership, these sessions can help health care workers to learn more about the interaction of patient and staff characteristics that can contribute to these incidents.

Convening Support Groups

People with mental illness benefit from support groups that focus on daily problems and the stress of dealing with a mental illness. These groups are useful throughout the continuum of care and help reduce the risk of suicide. In the hospital setting, the focus of the group can be simply sharing the experience of living with a mental illness. In the community, a regular support group can provide interaction with people with similar problems and issues. Friendships often develop from these groups. Using peer counseling and support groups is a component of recovery-oriented care, but research is needed to understand these groups' impact on care (Chien et al., 2019).

Implementing Milieu Therapy

Individuals with schizophrenia may be hospitalized or may live in group homes for a long period of time. The challenge is helping people who are unable to live with family members to live harmoniously with strangers who have similar interpersonal difficulties. Arranging the treatment environment to maximize therapy is crucial to the rehabilitation of the patient.

Developing Recovery-Oriented Rehabilitation Strategies

Rehabilitation strategies are used to support the individual's recovery and

integration into the community (see [Box 24.15](#)). Factors that have been shown to promote recovery include the following:

- Adjustment, coping, and reappraisal
- Responding to the illness
- Social support, close relationships, and belonging

Factors that have a negative impact on the process of recovery include (1) negative interactions and isolation, (2) internal barriers, and (3) uncertainty and hopelessness (Soundy et al., 2015). Community-based psychosocial rehabilitation programs usually offer long-term intensive case management services to adults with schizophrenia. Programs provide a continuum of services to meet the changing needs of people with psychiatric disabilities. Patients set rehabilitation goals, and services are then provided to help “clients” (most programs do not use the term *patients*) reach their goals. Services range from daily home visits to providing transportation, occupational training and supported employment, and group support. Assertive community treatment (ACT) is one example of these types of services and has a solid base of evidence to support its use (Thorning & Dixon, 2020).

Evaluation and Treatment Outcomes

Outcome research related to schizophrenia has redefined previous ways of thinking about the course of the disorder. Schizophrenia was formerly considered to have a progressively long-term and downward course, but it is now known that schizophrenia can be successfully treated and recovery is possible (Vita & Barlati, 2018). In one older but significant study, the researchers interviewed patients 20 to 25 years after diagnosis and found that 50% to 66% experienced significant improvement or recovery (Harding et al., 1987). This study is important because it occurred before the development of second-generation antipsychotic agents. Today, we can be hopeful that even more people can experience improvement or recover from schizophrenia.

BOX 24.15

A Brother's Perspective

A sibling describes his brother with schizophrenia and the importance of both medications and relationships.

In 1998, at the age of 40 years, Robert was admitted to a psychiatric hospital. His brother was told at the time that he would never be able to live independently, and even if discharged, would only be repeatedly hospitalized. Robert had a long history of treatment and in 1998 he had received various types of antipsychotic medications, but he had not received any of the “new atypical variety.” He was prescribed one of these drugs, and within months, the staff who had predicted the most discouraging of outcomes told Robert’s brother that he was in the midst of a miraculous recovery—his thinking was clear and free from delusions and they were preparing Robert’s discharge.

A few weeks into the discharge planning, Robert called his brother; Robert was distressed because his social worker, whom Robert had known for years from a prior hospitalization, was leaving. The social worker had been abruptly transferred to another hospital. Robert deteriorated rapidly into tantrums, hallucinations, and dangerous behaviors. His discharge was put on hold. Robert’s brother’s rhetorical question was, “What was the difference between Robert on the same medication on Monday, when he was all right, and Tuesday, when he no longer was?” His answer to Robert’s condition was the loss of an important relationship.

Robert is now living in a community-based home where the dedicated staff members have shown that they can maintain rehospitalization rates below 3%.

Robert’s brother has interviewed many former psychiatric patients for a book. He found that every one of his interviewees, while attributing their recovery to medications or finding God, or a particular program, also identified an important relationship with one human being who believed in their ability to recover. Most of the time, this person was a professional, such as a social worker, a nurse, or a doctor. Sometimes, however, it was a member of the clergy or family member. A believing relationship....

Robert’s brother concluded, “Let’s provide a range of medications, and let’s study their effectiveness, but let’s remember that the pill is the ultimate downsizing. Let’s find resources to give people afflicted with mental illness what all of us need: fellow human beings upon whom we can depend on to help us through our dark times and, once through, to emerge into gloriously imperfect lives.”

For nurses, it is important to remember that it is not what we do *to* people, but rather, what we do *with* people: give hope, listen to their dreams, help them find ways to get as close as they can.

Adapted from Neugeboren, J. (2006). Meds alone couldn’t bring Robert back. *Newsweek*. National Empowerment Center. Retrieved February 20, 2021 from <http://power2u.org/meds-alone-couldnt-bring-robert-back/>

Continuum of Care

Continuity of care has been identified as a primary strategy for recovery because individuals with schizophrenia are at risk for becoming “lost” to services if left alone after discharge. Discharge planning encourages follow-up care in the community. In fact, many state mental health systems require an outpatient appointment before discharge. Treatment of people with schizophrenia occurs across a variety of settings. Not only inpatient hospitalization but also partial hospitalization, day treatment, and crisis stabilization can be used effectively.

Emergency Care

Emergency care ideally takes place in a hospital emergency department, but often the crisis occurs in the home. Patients are usually relapsing and do not recognize their bizarre or aggressive behaviors as symptoms. A specially trained crisis team is sent to assess the emergency and recommend further treatment. In the emergency department, patients are brought not only because of relapse but also because of medication side effects or water intoxication. Nurses should refer to the previous discussion for nursing management.

Inpatient-Focused Care

Inpatient hospitalizations are brief and focus on stabilization. Many times, patients are involuntarily admitted for a short period (see [Chapter 4](#)). During the stabilization period, the status is changed to voluntary admission, whereby the patient agrees to treatment.

Community Care

Most of the care of persons with schizophrenia is provided in the community through publicly supported recovery-oriented mental health delivery systems. The recovery journey can be long and require a variety of services such as ACT, outpatient therapy, case management, and psychosocial rehabilitation, including clubhouse programs. While the patient is in the community, their health care should be integrated with physical health care. Nurses should be especially vigilant that patients with mental illnesses receive proper primary and medical health care.

NCLEXNOTE Priorities in the patient with acute symptoms of schizophrenia include managing psychosis and keeping the patient safe and free from harming themselves or others. In the community, the priorities are preventing relapse, maintaining psychosocial functioning, engaging in psychoeducation, improving quality of life, and instilling hope.

In some cases, it is not the disorder itself that threatens the mental health of

the person with schizophrenia but the stresses of trying to receive care and services. Health care systems are complex and are often at the mercy of outdated policies. Development of assertiveness and conflict resolution skills can help the person in negotiating access to systems that will provide services. Developing a positive support system for stressful periods helps promote a positive outcome.

Virtual Mental Health Care

Telehealth is being used more broadly for many conditions. It is helpful for circumstances where physical distance in rural communities is common or physical distance during pandemics is required. People with schizophrenia who require supportive regular contacts with provider services for counseling, medication and side effect reviews, and assertive community engagement can benefit from telephone or computer-based conferencing. Mobile telephone applications are being developed at a rapid pace as well. These applications can help people to monitor health-related activities like exercise and diet. They can provide education and interventions such as cognitive-behavioral treatment or mindfulness activities. However, the effectiveness of providing care to people with schizophrenia over distances and with mobile applications needs ongoing evaluation to determine to whom these services accrue the most value.

Integration with Primary Care

Traditionally, mental health problems were treated separately from medical needs. It was not uncommon for there to be little connection between the treatment of mental disorders and medical disorders. We now know that a person cannot successfully recover unless physical and mental health care are integrated. The medical needs of persons with schizophrenia are significant and require treatment. There should be a systematic coordination of general and behavior health. Ideally, the patient would have one record where all care would be documented.

Treatment interventions for mental disorders impact the general health status of the person. Frequent communication with primary care providers allows monitoring and adjustment of medical treatment. Medication interactions are a concern when patients are receiving medications from several different

clinicians.

SCHIZOAFFECTIVE DISORDER

SAD, a complex and persistent psychiatric illness, is one of the schizophrenia spectrum disorders. SAD is characterized by periods of intense symptom exacerbation alternating with periods of adequate psychosocial functioning. This disorder is at times marked by psychosis, at other times, by mood disturbance. When psychosis and mood disturbance occur at the same time, a diagnosis of SAD is made (APA, 2013). Patients with SAD are more likely to exhibit persistent psychosis than are patients with a mood disorder. They feel that they are on a “chronic roller coaster ride” of symptoms that are often difficult to manage.

The long-term outcome of SAD is generally better than that of schizophrenia but worse than that of mood disorder. These patients resemble the mood disorder group in work function (see [Chapter 25](#)) and the schizophrenia group in social function. Persons with SAD usually have higher functioning than those with schizophrenia with severe negative symptoms and early onset of illness (Vardaxi et al., 2018).

Patients with SAD are at risk for suicide. The risk for suicide in patients with psychosis is increased by the presence of depression. Risk factors for suicide increase with the use of alcohol or substances, cigarette smoking, previous suicide attempts, and hospitalizations. Lack of regular social contact may be a factor that confers a long-term risk for suicidal behavior. This risk may be reduced by treatments designed to enhance social networks and contacts, and those focused on helping patients protect themselves against environmental stressors (Simon et al., 2019).

DELUSIONAL DISORDER

Delusional disorder is another schizophrenia spectrum disorder that is characterized by stable and well-systematized delusions that occur in the absence of other psychiatric disorders. A diagnosis of delusional disorder is based on the presence of one or more delusions for at least 1 month (APA, 2013). Delusions

are the primary symptom of this disorder. Apart from the direct impact of the delusion, psychosocial functioning is not markedly impaired. Examples of delusions include being followed, poisoned, infected, loved at a distance, or deceived by a spouse or lover.

The course of delusional disorder varies. The onset can be acute, or the disorder can occur gradually and become chronic. Patients usually live with delusions for years, rarely receiving psychiatric treatment unless their delusion relates to their health (somatic delusion), or they act on the basis of their delusion and violate legal or social rules. Full remissions can be followed by relapses. Behavior is remarkably normal except when the patient focuses on the delusion. At that time, thinking, attitudes, and mood may change abruptly. Personality does not usually change, but the patient is gradually and progressively involved with the delusional concern (APA, 2013). Delusional disorder is relatively uncommon in clinical settings.

OTHER PSYCHOTIC DISORDERS

Schizophreniform Disorder

The essential features of schizophreniform disorder are identical to those of schizophrenia, with the exception of the duration of the illness, which can be less than 6 months. Symptoms must be present for at least 1 month to be classified as a schizophreniform disorder. About one-third of the individuals recover, with the other two-thirds developing schizophrenia (APA, 2013).

Brief Psychotic Disorder

In brief psychotic disorder, the length of the episode is at least 1 day but less than 1 month. The onset is sudden and includes at least one of the positive symptoms of schizophrenia. The person generally experiences emotional turmoil or overwhelming confusion and rapid, intense shifts of affect (APA, 2013). Although episodes are brief, impairment can be severe, and supervision may be required to protect the person. Suicide is a risk, especially in younger patients.

Psychotic Disorders Attributable to a Substance

Patients with a psychotic disorder attributable to a substance present with prominent hallucinations or delusions that are the direct physiologic effects of a substance (e.g., drug use, toxin exposure) (APA, 2013). During intoxication, symptoms continue as long as the use of the substance continues. Withdrawal symptoms can last for as long as 4 weeks. Differential diagnosis is recommended.

SUMMARY OF KEY POINTS

- The schizophrenia spectrum disorders include schizophrenia, schizoaffective, delusional, and schizotypal disorders, brief psychotic disorder, schizophreniform disorder, and substance-medication-induced psychotic disorder (APA, 2013). Schizophrenia displays a complex of symptoms typically categorized as positive symptoms (i.e., those that exist but should not), such as delusions or hallucinations and disorganized thinking and behavior, and negative symptoms (characteristics that should be there but are lacking), such as alogia, avolition, anhedonia, and diminished emotional expression.
- The clinical course of schizophrenia begins with a prodromal period in childhood but is usually not recognized as a precursor to schizophrenia. An acute illness usually occurs in late adolescence and may require hospitalization when medication and recovery-oriented care are initiated. In recovery-oriented care, the nurse instills hope and partners with the person with schizophrenia to develop strategies to recover and lead a meaningful life.
- The cause of schizophrenia is thought to be related to genetic, neurodevelopmental, and neurotransmission dysfunction. Environmental stress can trigger acute episodes.
- Nursing assessment begins with the development of the therapeutic relationship and includes biologic, psychological, and social areas.

- Risk for self-injury or injury to others should always be included in the assessment. Establishment of baseline health information should be done before any medications are administered. Several standardized assessment tools are available to help assess characteristic abnormal motor movements.
- In general, the antipsychotic drugs used to treat patients with schizophrenia not only block dopamine transmission in the brain but also cause some troublesome and sometimes serious side effects, primarily anticholinergic side effects and extrapyramidal side effects (i.e., motor abnormalities). Newer second-generation antipsychotic agents block serotonin, as well as dopamine. The nurse should be familiar with these drugs, their possible side effects, and the interventions required to manage or control side effects.
- Extrapyramidal side effects of antipsychotic drugs may appear early in drug treatment and include acute parkinsonism or pseudoparkinsonism, acute dystonia, and akathisia, but they may also appear later after months or years of treatment. The primary example of late-appearing extrapyramidal side effects is tardive dyskinesia, which is a severe syndrome involving abnormal motor movements of the mouth, tongue, jaw, trunk, fingers, and toes.
- Health promotion and wellness interventions are important for overall well-being. People with schizophrenia spectrum disorders have special challenges because their medications can produce a negative impact on their physical health. Nurses can provide education and guidance for positive activity, exercise, and nutrition strategies that can counteract the effect of the medications and symptoms.
- Because schizophrenia is a lifetime disorder and patients require the continued support and care of mental health professionals and family or friends, one of the primary nursing interventions is ensuring that patients and families are properly educated regarding the course of the disorder, importance of drug maintenance, and need for consistent care and support. Positive interaction between patients and their families is key to the success of long-term treatments and outcomes.

- Other schizophrenia spectrum disorders (e.g., schizoaffective, delusional, and schizotypal disorders, brief psychotic disorder, schizophreniform disorder, and substance-medication-induced psychotic disorder) have symptoms similar to those of schizophrenia. Nursing care should be individualized based on a nursing assessment and current evidence related to care.

DEVELOPING CLINICAL JUDGEMENT

1. Describe steps that a nurse should use to make sure an assessment considers the cultural basis of a patient's hallucination and delusions.
2. A patient asks you to explain the difference between "positive" and "negative" symptoms. Develop an answer in "lay" terms for the question.
3. What steps might the nurse take to develop trust in a patient who has hallucinations and delusions and is frightened of other people?
4. Given that a patient with mental illness requires extra efforts at confidentiality and that patients with schizophrenia are often suspicious of their family members, explain ways you can help families and patients develop positive interactions.
5. A patient tells you that she has nothing to live for and everyone would be better off without her. You recognize that she may be having suicidal thoughts. What assessment questions would you ask? How would you help her develop a safety plan?
6. Discuss how therapeutic communication might have to change when working with a person with schizophrenia who is displaying primarily negative symptoms. How will you deal with the person's diminished response to you (both verbally and emotionally) when you are teaching or giving instructions for activities? How will you help the person compensate for some of their cognitive deficits?
7. A person with schizophrenia is admitted during a relapse. He said that he did not want to take his haloperidol anymore because it made him shake. The physician prescribes olanzapine. Develop a medication education plan that includes a comparison between olanzapine and haloperidol.
8. Mr. J. has just received a diagnosis of schizophrenia. During a recent outpatient visit, he confides to a nurse that he just has stress and does not think that he really has any psychiatric problems. Identify assessment areas that should be pursued before the patient leaves his appointment. How would you

confront the denial?

- j). A patient says his medication is not working. He is taking ziprasidone (Geodon) 40 mg twice a day. He tells you that he takes 40 mg before breakfast and 40 mg before bed. What interventions are needed to increase the effectiveness of the drug?
- k). Ms. J. was prescribed olanzapine (Zyprexa) for schizophrenia 1 month ago. Since her last monthly visit, she has gained 15 pounds. She is considering discontinuing her medication regimen because of the weight gain. Develop a plan to address her weight gain and her intention to discontinue her medication regimen.
- l). An older adult in a nursing home has a delusion that her husband is having an affair with her sister. Discuss nonpharmacologic nursing interventions that should be implemented with this patient. How would you explain her delusion to her husband? Develop a plan for clinical management, focusing on psychiatric nursing care, for a patient experiencing this condition. Identify health promotion activities for a person with schizophrenia who is gaining weight while taking antipsychotics might pursue.

Movie Viewing Guides

A Beautiful Mind: 2001. This Academy Award-winning movie starring Russell Crowe is based on the biography by Sylvia Naasar of the mathematician and Nobel Laureate John Nash. It presents the life and experiences of this man as he dealt with schizophrenia. It shows how his life and work were altered and the effects on his relationships with family and colleagues. The movie depicts how this man came to terms with his illness.

VIEWING POINTS: How does the treatment John Nash received in the 1950s differ from treatment today? How would you classify his symptoms according to the *DSM-5*? What is typical or problematic about Mr. Nash's relationship with the medications prescribed for him?

The Soloist: 2009. Based on a true story, this movie portrays the experience of a reporter/novelist named Steve Lopez (played by Robert Downey, Jr.) when he befriends Nathaniel Anthony Ayers, "the soloist" (played by Jamie Fox), who has severe, persistent, and untreated schizophrenia—and more importantly, exceptional musical talent. Formerly, a student at the prestigious Julliard School of Music in New York City, Ayers now lives on the streets of Los Angeles

playing his two-string violin. See also the book by the same title.

VIEWING POINTS: What are the risks and rewards of taking on such a personal relationship? How best can nurses advocate for individuals with severe mental illness (and their family and friends) when community resources are inadequate?

A Practice and Learn Activity related to the video on the topic of Schizophrenia is available at <http://thepoint.lww.com/Boyd7e>.

Unfolding Patient Stories: Linda Waterfall

Part 2

Recall from [Chapter 6](#) Linda Waterfall, a 48-year-old Native American diagnosed with an aggressive form of breast cancer. The recommended treatment is a mastectomy followed by chemotherapy, which she refused. What is the association between her illness and episodes of severe anxiety since diagnosis? How can a secondary mental health disorder contribute to her physical decline from cancer? What psychosocial assessments and interventions should the nurse incorporate into the plan of care to manage her anxiety?

Depression

Nursing Care of Persons with Depressive Moods and Suicidal Behavior

Barbara Jones Warren

KEYCONCEPTS

- depression
- mood
- suicidal behavior

LEARNING OBJECTIVES

After studying this chapter, you will be able to:

1. Discuss the role of mood and depression in mental disorders.
2. Delineate the clinical symptoms and course of major depressive disorder, including suicidal behavior.
3. Analyze the primary theories of major depressive disorder and their relationship to suicidal behavior.
4. Develop strategies to establish a patient-centered, recovery-oriented therapeutic relationship with a person with depression.
5. Apply a person-centered, recovery-oriented nursing process for persons with major depressive disorder, including those with suicidal behavior.
6. Identify medications used to treat people with depression and evaluate their effectiveness.
7. Develop wellness strategies for persons with depression.
8. Differentiate the type of mental health care provided in emergency care, inpatient-focused care, community care, and virtual mental health care.
9. Discuss the importance of integrated health care for persons with depression.
10. Describe other depressive disorders.

KEY TERMS

- Affect
- Anhedonia
- Cytokines
- Depression
- Depressive disorders
- Disruptive mood dysregulation disorder
- Major depressive disorder
- Persistent depressive disorder
- Premenstrual dysphoric disorder
- Serotonin syndrome
- Suicidality

Case Study

Louise is a 31-year-old woman who was admitted voluntarily to an inpatient mental health unit with depression with suicidal ideation. Louise and her

husband Brian have three children aged 9, 5, and 3 years.

INTRODUCTION

Most people have bad days or times of feeling sad and overwhelmed. When depressed feelings interfere with daily activities and relationships, however, this mood can impair judgment and contribute to negative views of the world. In some instances, depression is a symptom of a depressive disorder. This chapter discusses mood and depression, depressive disorders, and the related serious issue of suicidal behavior. Major depressive disorder is highlighted.

MOOD AND DEPRESSION

Normal variations in mood occur in response to life events. Normal mood variations (e.g., sadness, euphoria, and anxiety) are time limited and are not usually associated with significant functional impairment. Normal range of mood or affect, the expression of mood, varies considerably both within and among different cultures (Lin & Dmitrieva, 2019).

KEYCONCEPT Mood is a pervasive and sustained emotion that influences one's perception of the world and how one functions.

Affect, or outward emotional expression, is related to the concept of mood. Affect provides clues to the person's mood. For example, in depression, people often have limited facial expression. Several terms are used to describe affect, including the following:

- *Blunted*: significantly reduced intensity of emotional expression
- *Bright*: smiling, projection of a positive attitude
- *Flat*: absent or nearly absent affective expression
- *Inappropriate*: discordant affective expression accompanying the content of speech or ideation
- *Labile*: varied, rapid, and abrupt shifts in affective expression
- *Restricted or constricted*: mildly reduced in the range and intensity of emotional expression

Depression is the primary mood of depressive disorders. Depression can be overwhelming. Unless appropriately treated, depression persists over time, has a

significant negative effect on quality of life, and increases the risk of suicide (Lotfaliany et al., 2018; Tuithof et al., 2018).

KEYCONCEPT Depression is a common mental state characterized by sadness, loss of interest or pleasure, feelings of guilt or low self-worth, disturbed sleep or appetite, low energy, and poor concentration (American Psychiatric Association [APA], 2013; World Health Organization [WHO], 2019).

DEPRESSIVE DISORDERS OVERVIEW

When a sad mood interferes with daily life, a **depressive disorder** may exist that will benefit from treatment. In depressive disorders, a sad, irritable, or empty mood is present with somatic and cognitive changes that interfere with functioning. Several depressive disorders vary according to duration, timing, or cause (APA, 2013). These include disruptive mood dysregulation, major depressive disorder, persistent depressive (dysthymia), premenstrual dysphoric, substance-medication-induced, and other specified depressive and unspecified depressive disorders (APA, 2013). Disruptive mood dysregulation disorder is a new depressive disorder diagnostic category in the *DSM-5*.

The clinical symptoms and course of depressive phenomena are complex, dynamic, biopsychosocial processes involving life span and cultural aspects. Persons with depressive disorders experience a lower quality of life and are at greater risk for development of physical health problems than those who are not depressed. Depressive disorders are so widespread that they are generally diagnosed and treated in the primary care setting. Every nurse will have an opportunity to impact this pandemic health concern (WHO, 2019).

Depressive disorders are characterized by severe and debilitating depressive episodes and are associated with high levels of impairment in occupational, social, and physical functioning. They cause as much disability and distress to patients as chronic medical disorders. Frequently, they are undetected and untreated. Because suicide is a significant risk, these disorders are associated with premature death, especially in those individuals who have been hospitalized for depression (Bachman, 2018).

Depressive Disorders Across the Life Span

Children and Adolescents

Children with depressive disorders have symptoms similar to those seen in adults, with a few exceptions. They are more likely to have anxiety symptoms, such as fear of separation, and somatic symptoms, such as stomach aches and headaches. They may have less interaction with their peers and avoid play and recreational activities that they previously enjoyed. Mood may be irritable, rather than sad, especially in adolescents. See Chapter 37 for discussion of mental health disorders in children.

The risk of suicide, which peaks during the midadolescent years, is very real in children and adolescents. Mortality from suicide, which increases steadily through the teens, is the third leading cause of death for that age group. Findings from research indicate that chronic victimization increases the risk for depression and suicide ideation and attempts (Brunstein et al., 2019). The use of substances intensifies depressive symptomatology and the risk of suicide (Johns et al., 2018). See Chapter 22 for further discussion of suicide in children and adolescents.

Table 25-1: Interventions to Relieve Side Effects of Antidepressants

Side Effect	Pharmacologic	
	Intervention	Nonpharmacologic Intervention
Dry mouth, caries, inflammation of the mouth	Bethanechol 10–30 mg TID	Sugarless gum
	Pilocarpine drops	Sugarless lozenges
Nausea, vomiting	Change medication	6–8 cups of water per day
Weight gain	Change medication	Toothpaste for dry mouth
		Take medication with food
Urinary hesitation	Bethanechol 10–30 mg TID	Soda crackers, toast, tea
	Stool softener	Nutritionally balanced diet
Constipation		Daily exercise
		6–8 cups of water per day
		Diet rich in fresh fruits, vegetables, and whole grains

Diarrhea	OTC antidiarrheal	Maintain fluid intake
Orthostatic hypotension		Increase hydration Sit or stand up slowly
Drowsiness	Shift dosing time Lower medication dose Change medication	One caffeinated beverage at strategic time Do not drive when drowsy No alcohol or other recreational drugs Plan for rest time
Fatigue	Lower medication dose> Change medication	Daily exercise
Blurred vision	Bethanechol 10–30 mg TID Pilocarpine eye drops	Temporary use of magnifying lenses until body adjusts to medication
Flushing, sweating	Terazosin 1 mg once daily Lower medication dose Change medication	Frequent bathing Lightweight clothing
Tremor	β -blockers Lower medication dose	Reassure the patient that tremor may decrease as the patient adjusts to medication. Notify the caregiver if tremor interferes with daily functioning

OTC, over-the-counter; TID, three times a day.

Older Adults

Depression in older adults is often undetected or inadequately treated (Kok & Reynolds, 2017). However, it is estimated that 8% to 20% of older adults in the

community and as many as 37% in primary care settings experience depressive symptoms (Blazer & Steffens, 2015). Treatment is successful in 60% to 80%, but response to treatment is slower than in younger adults. Depression in older adults is often associated with chronic illnesses, such as heart disease, stroke, and cancer; symptoms may have a more somatic focus. Depressive symptomatology in this group may be confused with symptoms of bipolar, dementia, or cerebrovascular accidents. Hence, differential diagnosis may be required to ascertain the root and cause of symptoms. See Chapter 38 for further discussion of mental health disorders in older adults.

Suicide is a very serious risk for older adults, especially for men. Suicide rates peak during middle age, but a second peak occurs in those aged 75 years and older (Ivey-Stephenson et al., 2017) (see [Box 25.1](#) and [Chapter 22](#)).

BOX 25.1 **CLINICAL VIGNETTE**

Depression in an Older Adult

Bob is a 75-year-old man who lost his wife to cancer 18 months ago. Since his wife's death, he continued to live in their family home with his dog. His dog died 2 weeks ago and he has been despondent since then. His children found him sitting on the side of his bed with a loaded gun. He had already written a note that he did not want to be a burden and that his children would be better off without him. His family brought him to the emergency department for evaluation.

What Do You Think?

- What is the likelihood that Bob would actually kill himself?
- What do you think the next recovery-oriented strategy should be for Bob and his family?

MAJOR DEPRESSIVE DISORDER

Clinical Course

Major depressive disorder is commonly a progressively recurrent illness. With time, episodes tend to occur more frequently, become more severe, and are of a longer duration. Onset of depression may occur at any age. However, the initial onset may occur in puberty; the highest onset occurs within persons in their 20s (APA, 2013). Recurrences of depression are related to age of onset, increased intensity and severity of symptoms, and presence of psychosis, anxiety, and/or

personality features. The risk for relapse is higher in persons who have experienced initial symptoms at a younger age and incur other mental disorders (Hoertel et al., 2017).

Diagnostic Criteria

The primary diagnostic criterion for major depressive disorder is one or more moods, which is either a depressed mood or a loss of interest or pleasure in nearly all activities for at least 2 weeks. Four of seven additional symptoms must be present: disruption in sleep, appetite (or weight), concentration, or energy; psychomotor agitation or retardation; excessive guilt or feelings of worthlessness; and suicidal ideation ([Key Diagnostic Characteristics 25.1](#)>).

The incidence of misdiagnosis is often greater for persons who are treated by someone from culturally and ethnically different populations. Their explanation of their symptomatology may be expressed using different terminology, or the underrepresented group may feel uncomfortable with a clinician from a different culture (Hornberger et al., 2016; Warren, 2020).

Epidemiology and Risk Factors

The prevalence of major depressive disorder within the U.S. population is approximately 10.4% within a 12-month time period, with a lifetime prevalence of 20.6%. Individuals between the ages of 18 and 29 years have a higher prevalence rate than those persons aged 65 and older. Episodes typically last more than 6 months. Females have a higher prevalence rate than males (13.4% vs. 7.2%). Depression is more prevalent in younger adults, White adults, and Native American adults than among African American, Asian American, and Hispanic adults (Hasin et al., 2018).

Data from the WHO indicate that depression is the leading cause of years lost because of disability. More than 50% of persons who recover from an initial episode of depression experience another episode within 5 to 10 years (WHO, 2019).

Risk factors for the development of depression include the following:

- Prior episode of depression

- Family history of depressive disorder
- Lack of social support
- Lack of coping abilities
- Presence of life and environmental stressors
- Current substance use or abuse
- Medical and/or mental illness comorbidity

Consider Louise

Her sister died as a result of drowning 2 months ago. She has been telling her husband that she just wants to go to sleep and not wake up. What risk factors do you recognize?

Ethnicity and Culture

Culture can influence the experience and communication of symptoms of depression. Persons from culturally and ethnically diverse populations may formulate and describe their depressive symptomatology differently than in the clinical language used for diagnosis. For example, expressions such as “heartbrokenness” (Native American and Middle Eastern), “brain fog” (persons from the West Indies), “zar”, and “running amok” may be used in place of such terms as *depressed*, *sad*, *hopeless*, and *discouraged*.

In some cultures, somatic symptoms, rather than sadness or guilt, may predominate. Individuals from various Asian cultural groups may have complaints of weakness, tiredness, or imbalance. “Problems of the heart” (in Middle Eastern cultures) or of being “heartbroken” (among Native Americans of the Hopi tribe) may be the way that persons from these cultural groups express their depressive experiences. Culturally distinctive experiences need to be assessed to ascertain any presence of depressive disorder from a “normal” cultural emotional response (Pedersen et al., 2016).

Key Characteristics 25.1 • Major Depressive Disorder 296.XX

296.2X MAJOR DEPRESSIVE DISORDER, SINGLE EPISODE

296.3X MAJOR DEPRESSIVE DISORDER, RECURRENT

Diagnostic Criteria

- A. Five (or more) of the following symptoms have been present during the same 2-week period and represent a change from previous functioning; at least one of the symptoms is either (1) depressed mood or (2) loss of interest or pleasure.

Note: Do not include symptoms that are clearly attributable to another medical condition.

1. Depressed mood most of the day, nearly every day, as indicated by either subjective report (e.g., feels sad, empty, hopeless) or observation made by others (e.g., appears tearful). (**Note:** In children and adolescents, can be irritable mood.)
2. Markedly diminished interest or pleasure in all, or almost all, activities most of the day, nearly every day (as indicated by either subjective account or observation).
3. Significant weight loss when not dieting or weight gain (e.g., a change of more than 5% of body weight in a month), or decrease or increase in appetite nearly every day. (**Note:** In children, consider failure to make expected weight gain.)
4. Insomnia or hypersomnia nearly every day.
5. Psychomotor agitation or retardation nearly every day (observable by others, not merely subjective feelings of restlessness or being slowed down).
6. Fatigue or loss of energy nearly every day.
7. Feelings of worthlessness or excessive or inappropriate guilt (which may be delusional) nearly every day (not merely self-reproach or guilt about being sick).
8. Diminished ability to think or concentrate, or indecisiveness, nearly every day (either by subjective account or as observed by others).
9. Recurrent thoughts of death (not just fear of dying), recurrent suicidal ideation without a specific plan, or a suicide attempt or a specific plan for committing suicide.

The symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.

The episode is not attributable to the physiologic effects of a substance or to another medical condition.

- B. The symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.
- C. The episode is not attributable to the physiologic effects of a substance or to another medical condition.

Note: Criteria A to C represent a major depressive episode.

Note: Responses to a significant loss (e.g., bereavement, financial ruin, losses from a natural disaster, a serious medical illness, or disability) may include the feelings of intense sadness, rumination about the loss, insomnia, poor appetite, and weight loss noted in Criterion A, which may resemble a depressive episode. Although such symptoms may be understandable or considered appropriate to the loss, the presence of a major depressive episode in addition to the normal response to a significant loss should also be carefully considered. This decision inevitably requires the exercise of clinical judgment based on the individual's history and the cultural norms for the expression of distress in the context of loss.

The occurrence of the major depressive episode is not better explained by schizoaffective disorder, schizophrenia, schizophreniform disorder, delusional disorder, or other specified and unspecified schizophrenia spectrum and other psychotic disorders.

There has never been a manic episode or a hypomanic episode.

Note: This exclusion does not apply if all of the manic-like or hypomanic-like episodes are substance induced or are attributable to the physiologic effects of another medical condition.

Comorbidity

Major depressive disorders often co-occur with other psychiatric disorders, including those that are substance related. Depression often is associated with a variety of chronic medical conditions, particularly endocrine disorders, cardiovascular disease, and neurologic disorders (Lotfaliany et al., 2018).

Etiology

Biologic Theories

Genetic

Family, twin, and adoption studies demonstrate that genetic influences undoubtedly play a substantial role in the etiology of mood disorders. Major depressive disorder tends to run in families and has a heritable component. Currently, a major research effort is focusing on developing a more accurate paradigm regarding the contribution of genetic factors to the development of mood disorders (Howard et al., 2019).

Neurobiologic Hypotheses

Neurobiologic theories of the etiology of depression emerged in the 1950s. These theories posit that major depression is caused by a deficiency or dysregulation in central nervous system (CNS) concentrations of the neurotransmitters norepinephrine, dopamine, and serotonin or in their receptor functions. These hypotheses arose in part from observations that some pharmacologic agents elevated mood; subsequent studies identified their mechanisms of action. All antidepressants currently available have their therapeutic effects on these neurotransmitters or receptors. Current research continues to focus on the role of neurotransmitters and the neurobiology of depression (Joca et al., 2015).

Neuroendocrine and Neuropeptide Hypotheses

Major depressive disorder is associated with multiple endocrine alterations, specifically of the hypothalamic–pituitary–adrenal axis, the hypothalamic–pituitary–thyroid axis, the hypothalamic–growth hormone axis, and the hypothalamic–pituitary–gonadal axis. In addition, mounting evidence indicates that components of neuroendocrine axes (e.g., neuromodulatory peptides, such as corticotropin-releasing factor) may themselves contribute to depressive symptoms. Evidence also suggests that the secretion of these hypothalamic and growth hormones is controlled by many of the neurotransmitters implicated in the pathophysiology of depression (Gong et al., 2019).

Psychoneuroimmunology

Psychoneuroimmunology is a recent area of research into a diverse group of proteins known as *chemical messengers* between immune cells. These messengers, called cytokines, signal the brain and serve as mediators between immune and nerve cells. The brain is capable of influencing immune processes, and conversely, immunologic response can result in changes in brain activity. Increased cytokine levels are associated with depression and cognitive impairment indicating that inflammatory reactions are involved in the development of some mental health disorders (Himmerich et al., 2019).

Psychological Theories

Psychological theories that serve as a basis for nursing practice for persons with a mental health disorder are explained in [Chapter 7](#). Depression is one of the disorders treated from a psychological perspective. The following discussion identifies theoretical models often used in nursing care.

Psychodynamic Factors

Most psychodynamic theorists acknowledge some debt to Freud’s original conceptualization of the psychodynamics of depression, which ascribes the cause to an early lack of love, care, warmth, and protection and resultant anger, guilt, helplessness, and fear regarding the loss of love. The ensuing conflict between wanting to be loved and fear of rejection engenders pathologic self-punishment

(also conceptualized as aggression turned inward), self-rejection, low self-esteem, and depressive symptoms (see [Chapter 7](#)).

Behavioral Factors

The behavioral psychologists hold that depression primarily results from a severe reduction in rewarding activities or an increase in unpleasant events in one's life. The subsequent depression then leads to further restriction of activity, thereby decreasing the likelihood of experiencing pleasurable activities, which, in turn, intensifies the mood disturbance. Affected individuals often self-criticize and believe that they do not have the coping skills to deal with life's stresses. If family members believe that the person is "sick" and so lacks the necessary coping skills, they inadvertently reinforce the hopeless self-view of the depressed person.

Cognitive Factors

The cognitive approach maintains that irrational beliefs and negative distortions of thought about the self, the environment, and the future engender and perpetuate depressive effects (see [Chapter 7](#)). These depressive cognitions can be learned socially from family members or lack of experience in developing coping skills. These individuals think differently than nondepressed individuals and view their environment and themselves in negative ways. They blame themselves for any misfortunes that occur and see situations as being much worse than they are.

Developmental Factors

Developmental theorists posit that depression may result from the loss of a parent through death or separation or lack of emotionally adequate parenting. These factors may delay or prohibit the realization of appropriate developmental milestones.

Social Theories

Family Factors

Family theorists ascribe maladaptive patterns in family interactions as contributing to the onset of depression, particularly in the onset and occurrence of depression in younger individuals. A family becomes dysfunctional when interactions, decisions, or behaviors interfere with the positive development of the family and its individual members. Most families have periods of dysfunction, such as during a crisis or stressful situation when coping skills are not available. Unhealthy interactions within a family system can have a negative impact on one or more family members who do not have the coping skills to deal with the situation.

Environmental Factors

Depression has long been understood as a multifactorial disorder that occurs when environmental factors (e.g., death of family member) interact with the biologic and psychological makeup of the individual. Major depression may follow adverse or traumatic life events, especially those that involve the loss of an important human relationship or role in life. Social isolation, deprivation, and financial deprivation are associated with depression (Ge et al., 2017).

Family Response to Disorder

Depression in one family member affects the whole family. Spouses, children, parents, siblings, and friends experience frustration, guilt, and anger when a family member is immobilized and cannot function. It is often hard for others to understand the depth of the mood and how disabling it can be. Financial hardship can occur when the affected family member cannot work and instead spends days in bed. The lack of understanding and difficulty of living with a depressed person can lead to abuse. Women between the ages of 18 and 45 years constitute the majority of those experiencing depression. This incidence may affect women's ability to not only have productive lives and take care of themselves but to also take care of their children or other family members for whom they may have responsibility. Moreover, research indicates that the

incidence of depression may be higher in children whose mothers experience depression (Drury et al., 2016).

Remember Louise?

According to her husband, Louise has neglected her self-care and that of her children since her sister's death. Brian is very understanding and supportive of Louise's need to grieve, but he is concerned that this is more than grief. Brian says that he is afraid to leave her alone and the children are suffering. What recommendations would you suggest to Louise's husband? Are there indications that Louise's grief is developing into depression?

RECOVERY-ORIENTED CARE FOR PERSONS WITH DEPRESSIVE DISORDERS

Teamwork and Collaboration: Working Toward Recovery

Depressive disorders are the most commonly occurring mental disorders, but they are usually treated within the primary care setting, rather than psychiatric setting. Nursing practice requires a coordinated ongoing interaction among patients, families, and health care providers to deliver comprehensive services. This includes using the complementary skills of both psychiatric and medical care colleagues for forming overall goals, plans, and decisions and for providing continuity of care as needed. Collaborative care between the primary care provider and mental health specialist is also key to achieving remission of symptoms and physical well-being, restoring baseline occupational and psychosocial functioning, and reducing the likelihood of relapse or recurrence.

Individuals with depression enter mental health settings when their symptoms become so severe that hospitalization is needed, usually after suicide attempts, or if they self-refer because of incapacitation. Antidepressants are indicated for depression and are discussed later in this chapter. Interdisciplinary treatment of these disorders, which is often lifelong, needs to include a wide array of health professionals in all areas. The specific goals of treatment are as follows:

- Reduce or control symptoms and, if possible, eliminate signs and symptoms of the depressive syndrome.
- Improve occupational and psychosocial function as much as possible.
- Reduce the likelihood of relapse and recurrence through recovery-oriented strategies.

Cognitive and Interpersonal Therapies

Recent studies suggest that short-term cognitive and interpersonal therapies may be as effective as pharmacotherapy in milder depressions. In many instances, cognitive-behavioral therapy (CBT) is an effective strategy for preventing relapse in patients who have had only a partial response to pharmacotherapy alone (APA, 2013). CBT is implemented in individual or group therapy by a trained clinician.

- Interpersonal therapy seeks to recognize, explore, and resolve the interpersonal losses, role confusion and transitions, social isolation, and deficits in social skills that may precipitate depressive states. It maintains that losses must be mourned and related affects appreciated, role confusion and transitions must be recognized and resolved, and social skills deficits must be overcome to acquire social supports.

Combination Therapies

For patients with severe or recurrent major depressive disorder, the combination of psychotherapy (including interpersonal, cognitive-behavioral, behavior, brief dynamic, or dialectical behavioral therapies) and pharmacotherapy has been found to be superior to treatment using a single modality. Clinical practice guidelines suggest that the combination of medication and psychotherapy is particularly useful in more complex situations (e.g., depression in the context of concurrent, chronic general-medical, or other psychiatric disorders, or in patients who fail to experience complete response to either treatment alone). Psychotherapy, in combination with medication, is also used to address collateral issues, such as medication adherence or secondary psychosocial problems (Dunlop et al., 2019). If medications and psychotherapy are not effective, other options are available: electroconvulsive therapy (ECT), light therapy, and repetitive transcranial magnetic stimulation (rTMS), discussed later in the chapter.

Alternative Therapies

Alternative or complementary therapies are often used in the treatment of depression. Acupuncture, yoga or tai chi, meditation, guided imagery, and massage therapy are a few therapies that may be helpful to palliate depression. Music or art therapy is also used often in conjunction with medication or psychotherapy.

Safety Issues

The overriding concern for people with mood disorders is safety because these individuals may experience self-destructive thoughts and suicidal ideation. Hence, the assessment of possible suicide risk should be routinely conducted in any person who is depressed (see [Chapter 22](#)).

EVIDENCE-BASED NURSING CARE OF PERSONS WITH DEPRESSIVE DISORDER

An awareness of the risk factors for depression, a comprehensive and culturally competent mental health nursing assessment, history of illness, and past treatment are key to formulating a treatment or recovery plan and to evaluating outcomes. Interviewing a family member or close friend about the patient's day-to-day functioning and specific symptoms may help determine the course of the illness, current symptoms, and level of functioning. The family's level of support and understanding of the disorder also need to be assessed. See [Nursing Care Plan 25.1](#).

Mental Health Nursing Assessment

The mental health nursing assessment focuses on the physical consequences of the depression, as well as the psychosocial aspects. The symptoms of depression are similar to those of some medical problems or medication side effects. Often,

the mental health nurse is the only clinician who provides holistic care to a person with depression who is often treated by other disciplines.

Physical Health

The nursing assessment should include a physical systems review and thorough history of medical problems, with special attention to CNS function, endocrine function, anemia, chronic pain, autoimmune illness, diabetes mellitus, or menopause. Additional medical history includes surgeries, medical hospitalizations, head injuries, episodes of loss of consciousness, pregnancies, childbirths, miscarriages, and abortions. A complete list of prescribed and over-the-counter (OTC) medications and herbal supplements should be compiled, including the reason a medication was prescribed or its use discontinued. A physical examination is recommended with baseline vital signs and baseline laboratory tests, including a comprehensive blood chemistry panel, complete blood counts, liver function tests, thyroid function tests, urinalysis, and electrocardiograms (see [Chapter 11](#)).

The following symptoms are characteristics of depression and should be assessed:

- *Appetite and weight changes:* In major depression, changes from baseline include a decrease or increase in appetite with or without significant weight loss or gain (i.e., a change of more than 5% of body weight in 1 month). Weight loss occurs when the person is not dieting. Older adults with moderate-to-severe depression need to be assessed for dehydration as well as weight changes.
- *Sleep disturbance:* The most common sleep disturbance associated with major depression is insomnia, which is broken into three categories: initial insomnia (difficulty falling asleep), middle insomnia (waking up during the night and having difficulty returning to sleep), and terminal insomnia (waking too early and being unable to return to sleep). Less frequently, the sleep disturbance is hypersomnia (i.e., prolonged sleep episodes at night or increased daytime sleep). The individual with either insomnia or hypersomnia complains of not feeling rested on awakening.
- *Tiredness, decreased energy, and fatigue:* Fatigue associated with depression is a subjective experience of feeling tired regardless of how much sleep or physical activity a person has had. Even the smallest tasks require substantial effort.

NCLEXNOTE In determining severity of depressive symptoms, nursing assessment should explore physical changes in appetite and sleep patterns and decreased energy. Remember these three major assessment categories. A question in the test may state several patient symptoms and expect the student to

recognize that the patient being described is depressed.

NURSING CARE PLAN 25.1

The Person with Depressive Disorder

Louise is a 31-year-old woman with a diagnosis of major depressive disorder with suicidal ideation. She feels hopeless, helpless, and worthless. She is grieving the loss of her sister and also feels that she has failed her. She believes her family would be better off without her. She has lost interest and pleasure in everything that she used to enjoy. She lacks energy to get out of bed or do basic self-care. Her thoughts are negative and distorted. Her facial expression is sad and restricted. She has difficulty smiling or seeing humor in a situation.

Setting: Intensive Care Psychiatric Unit in a General Hospital

Baseline Assessment: Louise is oriented to time, place, and person. She is dressed in a sweatshirt and sweatpants. Her appearance is disheveled, she has a slight body odor, and her hair is not combed. Her physical care plan reveals a recent 15 lb weight loss, insomnia, and loss of appetite. Her vital signs and laboratory values are within normal limits. She denies having a suicidal plan but says she wants to go to sleep and not wake up. Her husband said he is very worried about her because “she is physically there but not available to any of us.”

Associated Psychiatric Diagnosis
Major depressive disorder

Medications
Initiated escitalopram (Lexapro) 20 mg/day

Priority of Care: Safety and Suicide Prevention

Important Characteristics
Feelings of hopelessness
Expresses desire to die
Lethal means available

Associated Considerations
Recently lost sister
Believes she is a burden to family

Outcomes

Initial
Remain free from self-harm.
Identify factors that led to suicidal intent and methods for managing

Discharge
Agrees to continue with outpatient therapy.

suicidal impulses if they return. Accept treatment of depression by trying the SSRI antidepressants and psychotherapy.	Agrees to take antidepressant. Agrees that family can remove gun(s) from home.
---	---

Interventions

Interventions	Rationale	Ongoing Assessment
Initiate a nurse–patient relationship by demonstrating an acceptance of Louise as a worthwhile human being through the use of nonjudgmental statements and behavior.	A sense of worthlessness often underlies suicide ideation. The positive therapeutic relationship can support hopefulness.	Assess the stages of the relationship and determine whether a therapeutic relationship is actually being formed. Identify indicators of trust.
Initiate suicide precautions per hospital policy.	Safety of the individual is a priority with people who have suicide ideation.	Determine intent to harm self—plan and means.
Discuss with family members removal of lethal weapons from home.	Suicidal behavior is often impulsive. Removing means of suicide may prevent persons from acting on impulsive thoughts.	Follow-up with the patient and family member about removing lethal weapons.

Evaluation

Outcomes	Revised Outcomes	Interventions
Has not harmed herself.	Identify strategies to resist suicide attempts in the future.	Discuss antecedents that led to the suicide attempt. Discuss initiation of an antidepressant.

Priority of Care: Hopelessness

Important Characteristics	Associated Considerations
Decreased affect Decreased appetite Insomnia Lack of initiative States she has no reason to live	Loss of sister

Outcomes

Initial	Discharge
Accept support through the nurse–patient relationship. Identify hopelessness as a pervasive feeling.	Express feelings of being hopeful for the future.

Interventions

Interventions	Rationale	Ongoing Assessment
Establish a trusting therapeutic relationship.	Therapeutic relationships are effective in instilling hope.	Observe verbal and nonverbal cues that increase communications.
Enhance Louise's sense of hope by being attentive, validating your interpretation of what is being said or experienced, and helping him verbalize what she is expressing nonverbally.	By showing respect for the patient as a human being who is worth listening to, the nurse can support and help build the patient's sense of self.	Determine whether the patient confirms interpretation of situation and if she can verbalize what she is expressing nonverbally.
Assist to reframe and redefine negative statements ("not a burden but missing your sister").	Reframing an event positively rather than negatively can help the patient view the situation in an alternative way.	Assess whether Louise is feeling more hopeful.
Participate in a recovery group focusing on hope.	Group support can be very effective in discussing hope and identifying strategies to establish hopefulness.	Determine if the patient is attending group sessions and participating in discussions.
Evaluation		
Outcomes	Revised Outcomes	Interventions
Able to discuss future events in a positive manner.	Discuss specific plans for future events.	Continue with cognitive approaches when discussing future events.
Attending recovery group regularly.	None.	
SSRI, selective serotonin reuptake inhibitor.		

Consider This:

Recall that Louise has not been eating because she is not hungry and has lost 15 lb over the last 6 weeks. She is also not sleeping well. She wakes up during the middle of the night and cannot go back to sleep. What symptoms of depression is Louise experiencing?

Physical Functioning

Physical functioning is an integrated component of a person's biopsychosocial existence. It is really the manner in which a person matches their age-appropriate developmental stage and is able to successfully enact daily tasks of living. It

focuses on how healthy a person is and how well they take care of themselves (Warren, 2020).

Medication

In addition to a physical assessment, an assessment of current medications should be completed. The frequency and dosage of prescribed medications, OTC medications, and use of herbal or culturally related medication treatments should be explored. In depression, the nurse must always assess the possible lethality of the medication the patient is taking. For example, if a patient has sleeping medications at home, the individual should be further queried about the number of pills in the bottle. Patients also need to be assessed for their use of alcohol, marijuana, and other mood-altering medications, as well as herbal substances because of the potential for drug–drug interactions. For example, patients taking antidepressants that affect serotonin regulation could also be taking St. John wort (*Hypericum perforatum*) to fight depression. The combined drug and herb could interact to cause serotonin syndrome (altered mental status, autonomic dysfunction, and neuromuscular abnormalities). SAME (S-adenosyl-L-methionine) is another herbal preparation that patients may be taking. Patients need to be advised of possible adverse side effects of SAME taken with any prescribed antidepressant because the exact action of this herb remains unclear.

Substance Use Assessment

A significant proportion of persons (40%–60%) with a depressive disorder have a substance use disorder also. Conversely, alcohol use disorder increases the risk of a depressive disorder more than fourfold (Tolliver & Anton, 2015). These co-occurring disorders have an adverse impact on both mood and substance use outcomes. It is important that the nurse assesses the use of substances and consider the impact of co-occurring disorders (see Chapter 42).

Psychosocial Assessment

The psychosocial assessment for persons who have major depressive disorder includes the mental status (mood and affect, thought processes and content, cognition, memory, and attention), coping skills, developmental history, psychiatric family history, patterns of relationships, quality of support system, education, work history, and impact of physical or sexual abuse on interpersonal function. See [Chapter 11](#). The nurse should identify the individual's strengths, as well as problem areas, by asking the patient to describe their thoughts, feelings and behaviors before the current depressive episode. Including a family member or close friend in the assessment process can be helpful. The following discussion identifies key assessment areas for a person who is depressed.

Mental Status and Appearance

Mood and Affect

The person with major depressive disorder has a sustained period of feeling depressed, sad, or hopeless and may experience anhedonia (loss of interest or pleasure). The patient may report “not caring any more” or not feeling any enjoyment in activities that were previously considered pleasurable. In some individuals, this may include a decrease in or loss of libido (i.e., sexual interest or desire) and sexual function. In others, irritability and anger are signs of depression, especially in those who deny being depressed. Individuals often describe themselves as depressed, sad, hopeless, discouraged, or “down in the dumps”. If individuals complain of feeling “blah”, having no feelings, constantly tired, or feeling anxious, a depressed mood can sometimes be inferred from their facial expression and demeanor (APA, 2013).

Numerous assessment scales are available for assessing depression. Easily administered self-report questionnaires can be valuable detection tools. These questionnaires cannot be the sole basis for making a diagnosis of major depressive episode, but they are sensitive to depressive symptoms. The following are five commonly used self-report scales:

- General Health Questionnaire (GHQ)
- Center for Epidemiological Studies Depression Scale (CES-D)
- Beck Depression Inventory (BDI)
- Zung Self-Rating Depression Scale (SDS)
- PRIME-MD

Clinician-completed rating scales may be more sensitive to improvement in the course of treatment, can assess symptoms in relationship to the depressive diagnostic criteria, and may have a slightly greater specificity than do self-report questionnaires in detecting depression. These include the following:

- Hamilton Rating Scale for Depression (HAM-D)
- Montgomery-Asberg Depression Rating Scale (MADRS)
- National Institute of Mental Health Diagnostic Interview Schedule (DIS)

Thought Content

Depressed individuals often have an unrealistic negative evaluation of their worth or have guilty preoccupations or ruminations about minor past failings. Such individuals often misinterpret neutral or trivial day-to-day events as evidence of personal defects. They may also have an exaggerated sense of responsibility for untoward events. As a result, they feel hopeless, helpless, worthless, and powerless. The possibility of disorganized thought processes (e.g., tangential or circumstantial thinking) and perceptual disturbances (e.g., hallucinations, delusions) should also be included in the assessment.

Cognition and Memory

Many individuals with depression report an impaired ability to think, concentrate, or make decisions. They may appear easily distracted or complain of memory difficulties. In older adults with major depression, memory difficulties may be the chief complaint and may be mistaken for early signs of dementia (pseudodementia) (APA, 2013). When the depression is fully treated, the memory problem often improves or fully resolves.

Behavioral Responses

Changes in patterns of relating (especially social withdrawal) and changes in level of occupational functioning are commonly reported and may represent a significant deterioration from baseline behavior. Increased use of “sick days” may occur. For people who are depressed, special attention should be given to the individual’s spiritual dimension and religious background.

Self-Concept

A positive self-esteem can be protective for the development of severe depression. A low self-esteem is associated with several health problems such as obesity, cardiovascular events, and depression (Alghawrien et al., 2020; Ngo et al., 2020). Assessing self-esteem helps in establishing goals and direction for treatment.

Stress and Coping Patterns

The individual should be assessed for coping patterns. How does the person cope with the everyday stresses of life? How does the person cope with the depression and how does the depression impact the person's ability to cope with daily stressors? The nurse helps the patient identify positive coping patterns such as meditating, talking to a loved one and negative coping patterns such as overeating and using alcohol or nonprescribed drugs.

Suicidal Behavior

Patients with major depressive disorder are at increased risk for suicide. The development of suicide behavior is a complex phenomenon because symptoms are often hidden or veiled by somatic symptoms.

KEYCONCEPT **Suicidal behavior** is the occurrence of persistent thought patterns and actions that indicate a person is thinking about, planning, or enacting suicide.

Suicidal ideation includes thoughts that range from a belief that others would be better off if the person were dead or thoughts of death (passive suicidal ideation) to actual specific plans for committing suicide (active suicidal ideation). See [Chapter 22](#). The frequency, intensity, and lethality of these thoughts can vary and can help to determine the seriousness of intent. The more specific the plan and the more accessible the means, the more serious becomes the intent. The risk for suicide needs to be initially assessed in patients who incur depressive disorders as well as reassessed throughout the course of treatment.

Suicidal ideation is not a normal reaction to stress. Persons who express any

suicidal ideation need immediate mental health assessment regarding the depth of their thoughts and intentions. Risk factors for suicide ideation include lack of availability and inadequacy of social supports; family violence, including physical or sexual abuse; past history of suicidal ideation or behavior; presence of psychosis or substance use or abuse; and decreased ability to control suicidal impulses. See [Chapter 22](#).

Ethnic and cultural differences exist regarding suicidal behavior. Men often use firearms. Women often use pills or other poisonous substances to commit suicide. Children often use suffocation. Data on suicide completion rates are reported highest in persons from Native Americans, Alaskan Natives, and those of non-Hispanic White descent. These rates are lowest for persons from Hispanic, non-Hispanic Black, and Asian and Pacific Islander descent. Ongoing research regarding suicide in veterans indicates that they have a higher risk than persons in the general population (Smigelsky et al., 2020). Psychological stress and previously diagnosed psychiatric disorders are major risk factors for veterans. Counseling and supportive services need to be provided to family and friends of persons who attempt or die by suicide because family and friends may experience feelings of grief, guilt, anger, and confusion (Link et al., 2020).

NCLEXNOTE The possibility of suicide should always be a priority with patients who are depressed. Assessment and documentation of suicide risk should always be included in patient care.

Strength Assessment

Throughout the assessment, the nurse should be observing for strengths such as positive physical health status, coping skills, and social support. The following questions may be used to determine a person's strength:

- When you have been depressed before, how did you cope with the feelings?
- What do you do to relax?
- Do you reach out to anyone when you are feeling down?
- When you are not depressed, what makes you feel good?

CLINICAL JUDGMENT

There are several symptoms and effects of depression that could potentially require nursing care. In collaboration with the individual, the nurse can establish priorities of care. Suicidal thoughts and behaviors are always the first priority. If a patient does not have suicidal thoughts, the nurse can focus on the physical impact of the depression, such as lack of sleep, loss of appetite, and lack of energy, to carry out daily routines. Feelings of hopelessness and low self-esteem are usually present and need attention. Many people who are depressed have difficulty making decisions. As the priorities are established, the results of the strength assessment should be identified. These strengths will help the person recover from the depressed state.

THERAPEUTIC RELATIONSHIP

One of the most effective tools for caring for any person with a mental disorder is the therapeutic relationship. For a person who is depressed, there are a number of effective approaches:

- Establishment and maintenance of a supportive relationship based on the incorporation of culturally competent interventions and strategies
- Availability in times of crisis
- Vigilance regarding danger to self and others
- Education about the illness and treatment goals
- Encouragement and feedback concerning progress
- Guidance regarding the patient's interactions with the personal and work environment
- Realistic goal setting and monitoring
- Support of individual strengths in treatment choices.

Interacting with individuals who are depressed is challenging because they tend to be withdrawn and have difficulty expressing feelings and engaging in interpersonal interactions. The therapeutic relationship can be strengthened through the use of cognitive interventions as well as the nurse's ability to win the patient's trust through the use of culturally competent strategies in the context of empathy ([Box 25.2](#)).

Cheerleading, or being overly cheerful to a person who is depressed, blocks communication and can be quite irritating to depressed patients. Nurses should avoid approaching patients with depression with an overly cheerful attitude. Instead, a calm, supportive empathic approach helps keep communication open.

NCLEXNOTE Establishing the patient–nurse relationship with a person who is depressed requires an empathic quiet approach that is grounded in the nurse’s understanding of the cultural needs of the patient.

MENTAL HEALTH NURSING INTERVENTIONS

Establishing Recovery and Wellness Goals

Nursing intervention selection is a collaborative process between the patient and the nurse. As goals and interventions are agreed by both the nurse and the patient, the person’s strengths (e.g., motivation to get better, resources, family support) should be emphasized in making treatment choices.

Physical Care

Because weeks or months of disturbed sleep patterns and nutritional imbalance only worsen depression, one of the first nursing interventions is helping the person re-establish normal sleep patterns and healthy nutrition. Supporting self-care management by encouraging patients to practice positive sleep hygiene and eat well-balanced meals regularly helps the patient move toward remission or recovery.

Deep-breathing exercises three times a day have been shown to reduce self-reported depressive symptoms within 4 weeks in patients with coronary heart disease ([Box 25.3](#)). Activity and exercise are also important for improving depressed mood state. Most people find that regular exercise is hard to maintain. People who are depressed may find it impossible. When teaching about exercise, it is important to start with the current level of patient activity and increase it slowly. For example, if the patient is spending most of the time in bed, encouraging the patient to get dressed every day and walk for 5 or 10 minutes may be all that patient can tolerate. Gradually, patients should be encouraged to have a regular exercise program and to slowly increase their food intake. These activities are consistent with wellness goals.

BOX 25.2 • THERAPEUTIC DIALOGUE: APPROACHING THE

DEPRESSED PATIENT

Louise is severely depressed and has not left her hospital room since admission to the mental health unit. She has missed breakfast and is not interested in taking a shower or getting dressed.

INEFFECTIVE APPROACH

Nurse: Hello, Louise. My name is Sally. How are you feeling today?

Louise: I didn't sleep last night and need to rest. Please go away.

Nurse: Sorry, but it is time to get up. You have already missed breakfast. You have to take a quick shower now to get to group on time.

Louise: I have no interest in taking a shower or going to group.

Nurse: Why are you here if you don't want to be treated?

Louise: Go away. I don't want you in this room.

EFFECTIVE APPROACH

Nurse: Good morning. My name is Sally. I am your nurse today.

Louise: I didn't sleep last night and need to rest. Please go away.

Nurse: You didn't sleep well last night?

Louise: No, I can't remember when I was able to sleep through the night?

Nurse: Oh, I see. Is that why you missed breakfast?

Louise: I'm just not hungry. I have no energy.

Nurse: Lack of appetite and lack of energy are very common when people are depressed.

Louise: Really?

Nurse: Yes, so let's take one step at a time. I'd like to help you get up.

Louise: Ok, I might be able to sit up.

Nurse: (Helps her sit up). Now, let's walk to the bathroom.

Louise: (Walks to the bathroom). Now what?

Nurse: Let's work on your AM care.

CRITICAL THINKING CHALLENGE

- What ineffective techniques did the nurse use in the first scenario and how did they impair

communication?

- What effective techniques did the nurse use in the second scenario and how did they facilitate communication?

Research for Evidence-Based Practice: Breathing Exercise and Cognitive-Behavioral Interventions

Chien, H., Chung, Y., Yeh, M., & Lee, J. F. (2015). Breathing exercise combined with cognitive behavioural intervention improves sleep quality and heart rate variability in major depression. *Journal of Clinical Nursing*, 24(21–22), 3206–3214.

QUESTION: Do CBT and breathing exercises improve sleep quality and heart rate variability in major depression?

METHODS: Eighty-nine participants completed this study. One group ($n = 43$) received CBT combined with a breathing relaxation exercise for 4 weeks and the other group ($n = 43$) did not. Sleep quality and heart rate variability were measured at baseline, posttest 1 and 2, and follow-up.

FINDINGS: The group using the cognitive-behavioral intervention with the breathing exercise improved sleep quality and variability of heart rate significantly more than the control group.
